THE 'NINTH BRIDGEWATER TREATISE.

A FRAGMENT.

BY

CHARLES BABBAGE, ESQ.

"We may thus, with the greatest propriety, deny to the mechanical philosophers and mathematicians of recent times any authority with regard to their views of the administration of the universe; we have no reason whatever to expect from their speculations any help, when we ascend to the first cause and supreme ruler of the universe. But we might perhaps go farther, and assert that they are in some respects less likely than men employed in other pursuits, to make any clear advance towards such a subject of speculation."—*Bridgewater Treatise, by the* REV. WM. WHEWELL, p. 334.

ADVERTISEMENT TO THE SECOND EDITION.

THE following are the principal alterations in the Second Edition :—

The Chapter on Hume's Argument against Miracles has been nearly re-written, and the Note in the Appendix, to which it refers, has been so enlarged, as to meet all the interpretations which I have been able to suppose of that author's meaning.

The Chapter next following contains an examination of a difficulty which would naturally present itself to any one who had pursued the reasoning in the previous Chapter and its appended Note. I thought it better to state the difficulty, with what I conceive to be an answer, than to leave the reader to the chance of observing it, without the aid which he might justly claim from one who had previously gone over the same ground.

A new Chapter is then introduced, On the Nature of a Superintending Providence.

I have added in the Notes a very interesting letter from Sir John Herschel to Mr. Lyell, on the theory of isothermal surfaces, as connected with Geology.

I have again read, with much attention, the chapters in Mr. Whewell's *Bridgewater Treatise*, which bear upon the question of the effect of the pursuits of science on our belief in natural religion, and I confess that I am unable to alter the opinion I have already expressed upon that subject,—that they give support to those who maintain that the pursuits of science are in general unfavourable to religion. Of the injustice of that opinion, and of the individual injury which it occasionally inflicts, additional evidence has been presented to me, since the publication of the First Edition.

In endeavouring to understand the meaning and spirit of the author, I find it difficult to interpret such passages as the following, which is stated to embody the substance of his opinions :—

“ If the mathematician set out on religious reasonings, thinking that his mathematical knowledge alone must bring him into a nearer proximity to his Maker and Master, he will, I fear, find that the road is interrupted by a wide chasm, and he may, perhaps, turn back frustrated and hopeless. It is only by rising above his mathematics and his

“ physics ;—by recognising the utter dissimilarity of
“ moral and religious grounds of belief, from mathe-
“ matical and physical reasonings upon established
“ laws of nature ;—that he can make his way to the
“ conviction of a moral constitution and providential
“ government of the world ; and if the mathematical
“ or physical philosopher so habituate his mind, that
“ it is difficult for him thus to elevate himself into a
“ higher region than that of mathematical proof and
“ physical consequence, I cannot but think he does
“ damage to his power of judging on those other
“ subjects.”

This passage is one of those which is likely to be misunderstood, and which may be adduced by others in the support of views which it is impossible to suppose Mr. Whewell to entertain. If, by “ rising above his mathematics and physics,” it is meant, that inquiry into the relation of man to his Maker, is of more importance to his welfare than those other subjects, then it is a proposition which scarcely requires to be asserted, because it has never been denied. Even the atheist, who has arrived, by reasoning, at his desolate conclusion, would not fail to admit its truth, by attending to any *new* argument which might be proposed against his creed. But if it is meant, that there is a “ higher region ” of *evidence* than that of “ mathematical proof and physical consequence,” then it is in my opinion utterly and

completely erroneous; and as I am confident this erroneous light will be that in which the statement will be understood by many, I think it necessary to state distinctly what appears to me the relative position of the subjects in discussion.

First, The truths of pure mathematics are necessary truths; they are of such a nature, that to suppose the reverse, involves a contradiction.

Secondly, The laws of nature, on which physical reasonings are founded, although some of them are considered as necessary truths, depend, in many instances, on the testimony of our senses. These derive their highest confirmation from the aid of pure mathematics, by which innumerable consequences, previously unobserved, are proved to result from them.

Thirdly, The truths of natural religion rest also on the testimony of our external senses, but united with that internal consciousness of intention or design which we experience in our own breast, and from which we infer similar powers in other beings. Many of the facts on which the conclusions of natural religion are founded, derive their chief importance from the aid supplied by the united power of the two former classes, and the amount and value of this support will be enlarged with the advance of those sciences.

Fourthly, Revealed religion rests on human testimony; and on that alone. Its first and greatest support arises from natural religion. I have endeavoured in one chapter of the present volume to show, that, notwithstanding the weakening effect of transmission upon testimony, a time may arrive when, by the progress of knowledge, internal evidence of the truth of revelation may start into existence with all the force that can be derived from the testimony of the senses.

The first class of truths then (those of Pure Mathematics) appears to rest on necessity. The second, (the Laws of Nature,) on necessity and our external senses. The third, (those of Natural Religion,) on our external senses and internal consciousness. The last, (those of Revelation,) on human testimony. If they admit of any classification, as subjects having a common resemblance, or as possessing different degrees of evidence, I have placed them in the only order which, in my opinion, is consistent with truth; convinced that it is more injurious to religion to overrate, than to undervalue the cogency of the evidence on which it rests.

POSTSCRIPT.

A volume, on the Connexion of Natural Science and Religion, by the Rev. J. Baden Powell, has just reached me; and whilst I am happy in having several of my arguments approved by so candid and competent an inquirer, I will here, at the author's request, correct an oversight into which he has inadvertently fallen, in commenting on the view taken respecting the interpretation of the Mosaic account of the Creation.

It is stated by Mr. Powell that the view I have proposed “amounts to an admission that it is impossible at the present day to fix any certain meaning on compositions of such antiquity, and so entirely destitute of all elucidation from cotemporary writings, as the Mosaic records.”

This statement is much more general than the opinion I have expressed, which is, that “the language of the Hebrews in times long subsequent to the date of that book (the books of Moses,) may not have so far changed as to prevent us from rightly understanding generally the history it narrates; but there appears to be no reasonable ground for venturing to pronounce with any confidence on the minute shades of meaning of allied words.”—*Ninth Bridgewater Treatise*, 1st Edit. p. 77.

PREFACE.

THE volume here presented to the public does not form a part of that series of works composed at the desire of the trustees who directed the application of the bequest of £8000, by the late Earl of Bridgewater, for the purpose of advancing arguments in favour of Natural Religion.

I have, however, thought, that in furthering the intentions of the testator, by publishing some reflections on that subject, I might be permitted to connect with them a title which has now become familiarly associated, in the public mind, with the evidences in favour of Natural Religion.

The Bridgewater Treatises were restricted by the founder to the subject of Natural Religion ; and I had intended not to have deviated from their example. In the single instance in which the question of miracles has been discussed, I was led so irresistibly, by the very nature of the illustrations employed in the former argument, to the view there proposed, that I trust to being excused for having ventured one step beyond the strict limits of that argument, by entering on the first connecting link between natural religion and revelation.

The same argument will produce very various

degrees of conviction on different minds ; and much of this difference will depend on the extent of previous information, and on the strength of the reasoning faculty in those to whom the argument is addressed. To the great variety, therefore, of the illustrations which have been adduced in proof of design and of benevolence in the works of the Creator, there can be no objection. In truth, to the cultivated eye of science, the origin and consequences of the mightiest hurricane, as well as those of the smallest leaf it scatters in its course, equally lead to the inference of a designing power, the more irresistibly the more extensive the knowledge which is brought to bear on those phenomena.

One of the chief defects of the Treatises above referred to appears to me to arise from their not pursuing the argument to a sufficient extent. When a multitude of apparently unconnected facts is traced up to some

common principle, we feel spontaneously an admiration for him who has explained to us the connexion; and if, advancing another stage in the investigation, he prove that other facts, apparently at variance with that principle, are not merely no exceptions, but are themselves inevitable consequences of its application, our admiration of the principle, and our respect for its discoverer, are still further enhanced.

But if this respect and admiration are yielded to the mere interpreter of Nature's laws, how much more exalted must those sentiments become when applied to the Being who called such principles into living existence by creating matter subservient to their dominion—whose mind, intimately cognizant of the remotest consequences of the present as well as of all other laws, decreed existence to that one alone, which should comprehend within its grasp the completion of its destiny—

which should require no future intervention to meet events unanticipated by its author, in whose omniscient mind we can conceive no infirmity of purpose—no change of intention!

The object of these pages, as of the *Bridge-water Treatises*, is to show that the power and knowledge of the great Creator of matter and of mind are unlimited. Deeply engaged in those other pursuits from which my chief arguments are drawn, I regret the impossibility of bestowing on their full development that time and attention which the difficulty and importance of the subject equally deserve; and in committing these fragments to the press, perhaps in too condensed a form, I wish them to be considered merely as suggestions intended to direct the reader's attention to lines of argument which appear to me new, and to views of nature which appear more magnificent, than those with which I was previously acquainted.

Probably I should not have been induced to place my reflections on the subject before the public, had I not, in common with other cultivators of the more abstract branches of mathematical science, felt that a prejudice, which I had believed to have been long eradicated from every cultivated mind, had lately received support, at least to a certain extent, from a chapter in the first* of the Bridgewater Treatises; and in a still greater degree, from a work of a far different order—one, however, which derived its only claim to notice from the circumstance of its appearing under the sanction of the University of Oxford.

The prejudice to which I allude is, *that the pursuits of science are unfavourable to religion.*

There are two classes of men most deeply impressed with the conviction of the very

* It was the first in the order of publication.

limited extent of human knowledge—those whose contracted information renders them eminent examples of the fact, and those whose wide grasp of many of its profoundest branches has taught them, by lengthened experience, that each accession to their stock but enables them to view a larger portion of its illimitable field. Those who belong to the first of these classes must acquire the alphabet of science, in order to understand knowledge, and the elements of modesty, to use it with dignity. When they have thus graduated in the “infant school” of philosophy, they may perhaps understand the argument, and perchance be worthy of a reply,—but not till then.

In that chapter of the first Bridgewater Treatise to which I have referred, the charge seems not even to be limited to those who pursue that branch of science which is conversant with the properties of pure number, and with abstractions of a like nature, but

applies to all who cultivate deductive processes of reasoning.

It is maintained by the author, that long application to such inquiries disqualifies the mind from duly appreciating the force of that kind of evidence which alone can be adduced in favour of Natural Theology.

“ We may thus, with the greatest propriety, deny to the mechanical philosophers and mathematicians of recent times any authority with regard to their views of the administration of the universe ; we have no reason whatever to expect from their speculations any help, when we ascend to the first cause and supreme ruler of the universe. But we might perhaps go farther, and assert that they are in some respects less likely than men employed in other pursuits, to make any clear advance towards such a subject of speculation.”—*Bridgewater Treatise, by the REV. WM. WHEWELL*, p. 334.

Admitting, for the sake of argument, that there have been individuals, possessed of high intellectual powers, successfully devoted to those subjects, who have arrived by reasoning at conclusions respecting the First Cause,

totally opposite to those entertained by Mr. Whewell and myself, I should still be very reluctant to endeavour to invalidate the influence of their conclusions, by any inquiry either into their intellectual or their moral character. Reasoning is to be combated and refuted by reasoning alone. Any endeavour to raise a prejudice, or throw the shadow of an imputation, either implies the existence of some latent misgiving in the minds of those who employ such weapons, or is a tacit admission that the question is beyond the grasp of one at least of the debaters.

Who that has studied their works ever dreamed of inquiring into the moral or intellectual character of Euclid or Archimedes, for the purpose of confirming or invalidating his belief in their conclusions? Who that possesses confidence in his own reason, justified by a laborious cultivation and successful exercise of that faculty, fails to anatomize and

refute the arguments, rather than analyze the mental or moral habits of those from whom he differs ?

The only case in which such extraneous matters can be fairly called in, is when facts are stated resting on testimony. Then it is not only just, but it is necessary for the sake of truth, to inquire into the habits of mind of him by whom they are adduced;—whether he possesses sufficient talent and precision to enable him to state precisely what his senses convey to him, and nothing more; or, if he receive information from others, whether he is credulous or cautious. In both cases, it is necessary to inquire into moral feelings, in order to be assured that there is no wilful mis-statement in the groundwork of his reasoning. And even when this is well established, it is still necessary to inquire whether he had any personal, professional, or pecuniary interest

which may insensibly have influenced his mind in one direction.

Such I conceive to be the sound distinction between those branches of knowledge resting on facts open to the observation of all, supported by reasoning addressed to the understandings of all, — and those other branches in which reasoning is mixed up with testimony. In the former, the argument is every thing—the character nothing: in the latter, the character must be sifted as well as the arguments.

Feeling convinced that the truths of Natural Religion rest on foundations far stronger than those of any human testimony; that they are impressed in indelible characters, by almighty power, on every fragment of the material world, I cannot but regret that reflections should have been made, in connexion with this subject, calculated to throw the least

shadow of doubt on evidence otherwise irresistible.

As, however, these views of the nature of the question may not bring that conviction to other minds, which they do to my own, and as *one* of the *disturbing forces* which act on our minds has been strongly put forward, it is but justice to state the whole of them. It requires but little insight into man's heart to perceive that profession and professional advancement — that power and wealth — have a far more frequent and more effective influence on his judgment than any mental habits he may be supposed to have cultivated.

It may be right then to state, that the author of these pages has always been an ardent but not an exclusive cultivator of some of the more abstract branches of mathematical science. In pursuing one of those inquiries,

amongst the most recondite and apparently the most removed from any practical application, he was struck with the bearing of some of the results which presented themselves, on the question of Natural Religion; and these he has endeavoured to place before the reader, in the following pages.

The author belongs to no profession in which he can hope for advancement, if he successfully advocate one side of the question, or in which his prospects can be injured by candidly stating any arguments on the other. He has not been invited by men high in the State, and deservedly respected, to strengthen that great basis which precedes all revelation, and on which it must all rest. Nor has any sum of money been assigned to him, that, whatever the mercantile success or failure of the present volume may be, he shall, on its publication, reap a large pecuniary reward.

Having chosen a career to which the institutions of the country hold out none of those great prizes that stimulate professional exertions, and which constrain men to yield a certain degree of deference to the opinions, sound or unsound, of their countrymen, he has, on the one hand, nothing to hope from their approbation, and, on the other, is equally exempt from any dread of their censure ; and, had his conviction been as strongly opposed to the doctrines this Fragment advocates, as it is in their favour, he would, had a fit occasion presented itself, fearlessly have laid before the world the arguments which had forced his mind to that conviction.

In conclusion, I have to express to my fellow-labourers in the cause, my hope that they will put no unkind interpretation on these remarks, which, founded on principles of human nature, are necessarily of general application ; that they will see that motives alien, in my

own opinion, to the subject, having been once introduced, candour to those who differ from us, as well as a deference to truth itself, compelled me to state them fully.

CHARLES BABBAGE.

DORSET-STREET,
MANCHESTER-SQUARE,
April 1837.

The following account of the origin of the Bridgewater Treatises, is extracted from one of those works:—

“ The Right Honourable and Reverend Francis Henry, Earl of Bridgewater, died in the month of February, 1829; and, by his last will and testament, bearing date the 25th of February, 1825, he directed certain Trustees therein named, to invest in the public funds the sum of eight thousand pounds sterling; this sum, with the accruing dividends thereon, to be held at the disposal of the President, for the time being, of the Royal Society of London, to be paid to the person or persons nominated by him. The testator further directed, that the person or persons selected by the said President should be appointed to write, print, and publish, one thousand copies of a work ‘On the Power, Wisdom, and Goodness of God, as manifested in the Creation;’ illustrating such work by all reasonable arguments, as, for instance, the variety and formation of God’s creatures in the animal, vegetable, and mineral kingdoms; the effect of digestion, and thereby of conversion; the construction of the hand of man, and an infinite variety of other arguments: as also by discoveries, ancient and modern, in arts, sciences, and the whole extent of literature. He desired, moreover, that the profits arising from the sale of the works so published should be paid to the authors of the works.

“ The late President of the Royal Society, Davies Gilbert, Esq.; requested the assistance of his Grace the Archbishop of Canterbury, and of the Bishop of London, in determining upon the best mode of carrying into effect the intentions of the testator. Acting with their advice, and with the concurrence of a nobleman immediately connected with the deceased, Mr. Davies Gilbert appointed eight gentlemen to write separate Treatises on the different branches of the subject.”

Of the eight gentlemen so appointed, four were of the clerical, and four of the medical, profession. Their names, and the subjects assigned to them, are as follows:—

1. The Rev. THOMAS CHALMERS, D.D., Professor of Divinity in the University of Edinburgh—"On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man."
 2. The Rev. WM. BUCKLAND, D.D., F.R.S., Canon of Christ Church, and Professor of Geology in the University of Oxford—"On Geology and Mineralogy."
 3. The Rev. WM. WHEWELL, M.A., F.R.S., Fellow of Trinity College, Cambridge—"On Astronomy and General Physics."
 4. The Rev. WM. KIRBY, M.A., F.R.S.—"On the History, Habits, and Instincts of Animals."
-
5. JOHN KIDD, M.D., F.R.S., Regius Professor of Medicine in the University of Oxford—"On the Adaptation of External Nature to the Physical Condition of Man."
 6. Sir CHARLES BELL, K.H., F.R.S.—"The Hand: its Mechanism and Vital Endowments, as evincing Design."
 7. PETER MARK ROGET, M.D., Fellow of, and Secretary to, the Royal Society—"On Animal and Vegetable Physiology."
 8. WM. PROUT, M.D., F.R.S.—"On Chemistry, Meteorology, and the Function of Digestion."

CHAP. I.

NATURE OF THE ARGUMENT.

THE notions we acquire of contrivance and design arise from comparing our observations on the works of other beings with the intentions of which we are conscious in our own undertakings. We take the highest and best of human faculties, and, exalting them in our imagination to an unlimited extent, endeavour to attain an imperfect conception of that Infinite Power which created every thing around us. In pursuing this course, it is evident that we are liable to impress upon the

notion of Deity thus shadowed out, many traces of those imperfections in our own limited faculties which are best known to those who have most deeply cultivated them. It is also evident that all those discoveries which arm human reason with new power, and all additions to our acquaintance with the material world, must from time to time render a revision of that notion necessary. The present seems to be a fit occasion for such a revision.

Many excellent and religious persons not deeply versed in what they mistakenly call "*human knowledge*," but which is in truth the interpretation of those laws that God himself has impressed on his creation, have endeavoured to discover proofs of design in a multitude of apparent adaptations of means to ends, and have represented the Deity as perpetually interfering, to alter for a time the laws he had previously ordained; thus by implication denying to him the possession

of that foresight which is the highest attribute of omnipotence. Minds of this order, insensible of the existence of that combining and generalising faculty which gives to human intellect its greatest development, and tied down by the trammels of their peculiar pursuits, have in their mistaken zeal not perceived their own unfitness for the mighty task, and have ventured to represent the Creator of the universe as fettered by the same infirmities as those by which their own limited faculties are subjugated. To causes of this kind must in some measure be attributed an opinion which has been industriously spread, that minds highly imbued with mathematical knowledge are disqualified, by the possession of that knowledge, and by the habits of mind produced during its acquisition, from rightly appreciating the works of the Creator.

At periods and in countries in which the knowledge of the priests exceeded that of the people, science has always been held up by the

former class as an object of regard, and its crafty possessors have too frequently defiled its purity by employing their knowledge for the delusion of the people. On the other hand, at times and in countries in which the knowledge of the people has advanced beyond that of the priesthood, the ministers of the temple have too often been afraid of the advance of knowledge, and have threatened with the displeasure of the Almighty those engaged in employing the faculties he has bestowed on the study of the works he has created. At the present period, when knowledge is so universally spread that neither class is far in advance of the other,—when every subject is submitted to unbounded discussion,—when it is at length fully acknowledged that truth alone can stand unshaken by perennial attacks, and that error, though for centuries triumphant, must fall at last, and leave behind no ashes from which it may revive, the authority of names has but little weight: facts and arguments are the basis of

creeds, and convictions so arrived at are the more deeply seated, and the more enduring, because they are not the wild fancies of passion or of impulse, but the deliberate results of reason and reflection.

It is a condition of our race that we must ever wade through error in our advance towards truth ; and it may even be said that in many cases we exhaust almost every variety of error before we attain the desired goal. But those truths, once reached by such a course, are always most highly valued ; and when, in addition to this, they have been exposed to every variety of attack which splendid talents quickened into energy by the keen perception of personal interests can suggest,—when they have revived undying from unmerited neglect ; when the anathema of spiritual, and the arm of secular power have been found as impotent in suppressing, as arguments were in refuting them, then they are indeed irresistible. Thus tried and

thus triumphant in the fiercest warfare of intellectual strife, even the temporary interests and furious passions which urge on the contest, contribute in no small measure to establish their value, and thus to render these truths the permanent heritage of our race.

Viewed in this light, the propagation of an error, although it may be unfavourable or fatal to the temporary interest of an individual, can never be long injurious to the cause of truth. It may, at a particular period, retard its progress for a while, but it repays the transitory injury by a benefit as permanent as the duration of the truth to which it was opposed. These reflections are offered for the purpose of proving that the toleration of the fullest discussion is most advantageous to truth. They are not offered as the apology for error; and whilst it is admitted that every person who wilfully puts forward arguments the soundness of which he doubts, incurs a deep responsibility, it is some satisfaction to

reflect that the delay likely to be thus occasioned to the great cause can be but small; and that those who in sincerity of heart maintain arguments which a more advanced state of knowledge shall prove to be erroneous, may yet ultimately contribute, by their very publication, to the speedier establishment of truth.

CHAP. II.

ARGUMENT IN FAVOUR OF DESIGN FROM THE
CHANGING OF LAWS IN NATURAL EVENTS.

THE estimate we form of the intellectual capacity of our race, is founded on an examination of those productions which have resulted from the loftiest flights of individual genius, or from the accumulated labours of generations of men, by whose long-continued exertions a body of science has been raised up, surpassing in its extent the creative powers of any individual, and demanding for its development a length of time, to which no single life extends.

The estimate we form of the Creator of the visible world rests ultimately on the same foundation. Conscious that we each of us employ, in our own productions, *means* intended

to accomplish the objects at which we aim, and tracing throughout the actions and inventions of our fellow-creatures the same intention,—judging also of their capacity by the fit selection they make of the means by which they work, we are irresistibly led, when we contemplate the natural world, to attempt to trace each existing fact presented to our senses to some precontrived arrangement, itself perhaps the consequence of a yet more general law; and where the most powerful aids by which we can assist our limited faculties fail in enabling us to detect such connexions, we still, and not the less, believe that a more extended inquiry, or higher powers, would enable us to discover them.

The greater the number of consequences resulting from any law, and the more they are foreseen, the greater the knowledge and intelligence we ascribe to the being by which it was ordained. In the earlier stages of our knowledge, we behold a multitude of distinct

laws, all harmonizing to produce results which we deem beneficial to our own species: as science advances, many of these minor laws are found to merge into some more general principles; and with its higher progress these secondary principles appear, in their turn, the mere consequences of some still more general law. Such has been the case in two of the most curious and most elaborately cultivated branches of human knowledge, the sciences of astronomy and optics. All analogy leads us to infer, and new discoveries continually direct our expectation to the idea, that the most extensive laws to which we have hitherto attained, converge to some few simple and general principles, by which the whole of the material universe is sustained, and from which its infinitely varied phenomena emerge as the necessary consequences.*

To illustrate the distinction between a system to which the restoring hand of its

* See Note A in the Appendix.

contriver is applied, either frequently or at distant intervals, and one which had received at its first formation the impress of the will of its author, foreseeing the varied but yet necessary laws of its action throughout the whole of its existence, we must have recourse to some machine, the produce of human skill. But far as all such engines must ever be placed at an immeasurable interval below the simplest of Nature's works, yet, from the vastness of those cycles which even human contrivance in some cases unfolds to our view, we may perhaps be enabled to form a faint estimate of the magnitude of that lowest step in the chain of reasoning, which leads us up to Nature's God.

The illustration which I shall here employ will be derived from the results afforded by the Calculating Engine;* and this I am the more disposed to use, because my own views respecting the extent of the laws of Nature

* The reader will find a short account of this engine in the Appendix, Note B.

were greatly enlarged by considering it, and also because it incidentally presents matter for reflection on the subject of inductive reasoning. Nor will any difficulty arise from the complexity of that engine; no knowledge of its mechanism, nor any acquaintance with mathematical science, are necessary for comprehending the illustration; it being sufficient merely to conceive that computations of great complexity *can* be effected by mechanical means.

Let the reader imagine that such an engine has been adjusted; that it is moved by a weight; and that he sits down before it, and observes a wheel, which moves through a small angle round its axis, at short intervals, presenting to his eye, successively, a series of numbers engraved on its divided circumference.

Let the figures thus seen be the series of natural numbers, 1, 2, 3, 4, 5, &c., each of which exceeds its immediate antecedent by unity.

Now, reader, let me ask how long you will have counted before you are firmly convinced that the engine, supposing its adjustments to remain unaltered, will continue whilst its motion is maintained, to produce the same series of natural numbers? Some minds perhaps are so constituted, that after passing the first hundred terms, they will be satisfied that they are acquainted with the law. After seeing five hundred terms, few will doubt; and after the fifty-thousandth term the propensity to believe that the succeeding term will be fifty thousand and one, will be almost irresistible. That term *will* be fifty thousand and one: the same regular succession will continue; the five-millionth and the fifty-millionth term will still appear in their expected order; and one unbroken chain of natural numbers will pass before your eyes, from *one* up to *one hundred million*.

True to the vast induction which has thus been made, the next succeeding term will be

one hundred million and one; but after that the next number presented by the rim of the wheel, instead of being one hundred million and two, is one hundred million *ten thousand* and two. The whole series from the commencement being thus:—

	100,360,009	
	100,450,010	
	100,550,011	
	
	

The law which *seemed* at first to govern this series fails at the hundred million and second term. That term is larger than we expected, by 10,000. The next term is larger than was anticipated, by 30,000, and the excess of each term above what we had expected forms the following table :—

	10,000
	30,000
•	60,000
	100,000
	150,000
	• • • • •
	• • • • •

being, in fact, the series of *triangular numbers*,* each multiplied by 10,000.

* The numbers 1, 3, 6, 10, 15, 21, 28, &c. are formed by adding the successive terms of the series of natural numbers thus ;

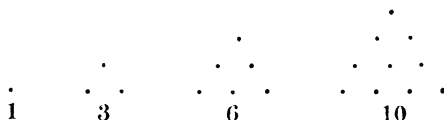

$$1 = 1.$$

$$1 + 2 = 3.$$

$$1 + 2 + 3 = 6.$$

$$1 + 2 + 3 + 4 = 10, \text{ \&c.}$$

They are called triangular numbers, because a number of points corresponding to any term can always be placed in the form of a triangle, for instance :—

If we still continue to observe the numbers presented by the wheel, we shall find, that for a hundred, or even for a thousand terms, they continue to follow the new law relating to the triangular numbers; but after watching them for 2761 terms, we find that *this* law fails in the case of the 2762d term.

If we continue to observe, we shall discover another law then coming into action, which also is dependent, but in a different manner, on triangular numbers. This will continue through about 1430 terms, when a new law is again introduced, which extends over about 950 terms; and this too, like all its predecessors, fails, and gives place to other laws, which appear at different intervals.

Now it must be remarked, that the law *that each number presented by the Engine is greater by unity than the preceding number*, which law the observer had deduced from *an induction of a hundred million instances*, was

not the true law that regulated its action ; and that the occurrence of the number 100,010,002 at the 100,000,002d term, was *as necessary a consequence* of the original adjustment, and might have been as fully foreknown at the commencement, as was the regular succession of any one of the intermediate numbers to its immediate antecedent. The same remark applies to the next *apparent* deviation from the new law, which was founded on an induction of 2761 terms, and to all the succeeding laws ; with this limitation only—that whilst their consecutive introduction at various definite intervals is a necessary consequence of the mechanical structure of the engine, our knowledge of analysis does not yet enable us to predict the periods at which the more distant laws will be introduced.

Such are some of the facts which, by a certain adjustment of the Calculating Engine, would be presented to the observer. Now, let him imagine another engine, offering to the

eye precisely the same figures in the same order of succession ; but let it be necessary for the maker of that other engine, previously to each apparent change in the law, to make some new adjustment in the structure of the engine itself, in order to accomplish the ends proposed. The first engine must be susceptible of having embodied in its mechanical structure, that more general law of which all the observed laws were but isolated portions,—a law so complicated, that analysis itself, in its present state, can scarcely grasp the whole question. The second engine might be of far simpler contrivance ; it must be capable of receiving the laws impressed upon it from without, but is incapable, by its own intrinsic structure, of changing, at definite periods, and in unlimited succession, those laws by which it acts. Which of these two engines would, in the reader's opinion, give the higher proof of skill in the contriver ? He cannot for a moment hesitate in pronouncing that that for which, after its original adjustment, no superintend-

ance is required, displays far greater ingenuity than that which demands, at every change in its law, the direct intervention of its contriver.

The engine we have been considering is but a very small portion (about fifteen figures) of a much larger one, which was preparing, and is partly executed; it was intended, when completed, that it should have presented at once to the eye about one hundred and thirty figures. In that more extended form which recent simplifications have enabled me to give to machinery constructed for the purpose of making calculations, it will be possible, by certain adjustments, to set the engine so that it shall produce the series of natural numbers in regular order, from unity up to a number expressed by more than a thousand places of figures. At the end of that term, another and a different law shall regulate the succeeding terms; this law shall continue in operation perhaps for a number of terms, expressed perhaps

by unity, followed by a thousand zeros, or 10^{1000} ; at which period a third law shall be introduced, and, like its predecessors, govern the figures produced by the engine during a third of those enormous periods. This change of laws might continue without limit; each individual law being destined to govern for millions of ages the calculations of the engine, and then give way to its successor to pursue a like career.*

Thus a series of laws, each simple in itself, successively spring into existence, at distances almost too great for human conception. The full expression of that wider law, which comprehends within it this unlimited sequence of minor consequences, may indeed be beyond the utmost reach of mathematical analysis:

* It has been supposed that ten turns of the handle of the calculating engine might be made in a minute, or about five hundred and twenty-six millions in a century. As in this case, each turn would make a calculation, after the lapse of a million of centuries, only the fifteenth place of figures would have been reached.

but of one remarkable fact, however, we are certain — that the mechanism brought into action for the purpose of changing the nature of the calculation from the production of the merest elementary operations into those highly complicated ones of which we speak, is itself of the simplest kind.

In contemplating the operations of laws so uniform during such immense periods, and then changing so completely their apparent nature, whilst the alterations are in fact only the *necessary* consequences of some far higher law, we can scarcely avoid remarking the analogy which they bear to several of the phenomena of nature.

The laws of animal life which regulate the caterpillar, seem totally distinct from those which, in the subsequent stage of its existence, govern the butterfly. The difference is still more remarkable in the transformations undergone by that class of animals which spend the first portion of their life beneath the

surface of the waters, and the latter part as inhabitants of air. It is true that the periods during which these laws continue to act are not, to our senses, enormous, like the mechanical ones above mentioned; but it cannot be doubted that, immeasurably more complex as they are, they were equally foreknown by their Author: and that the first creation of the egg of the moth, or the libellula, involved within its contrivance, as a necessary consequence, the whole of the subsequent transformations of every individual of their respective races.

In turning our views from these simple results of the juxtaposition of a few wheels, it is impossible not to perceive the parallel reasoning, which may be applied to the mighty and far more complex phenomena of nature. To call into existence all the variety of vegetable forms, as they become fitted to exist, by the successive adaptations of their parent earth, is undoubtedly a high exertion of creative power. When a rich vegetation has

covered the globe, to create animals adapted to that clothing, which, deriving nourishment from its luxuriance, shall gladden the face of nature, is not only a high but a benevolent exertion of creative power. To change, from time to time, after lengthened periods, the races which exist, as altered physical circumstances may render their abode more or less congenial to their habits, by allowing the natural extinction of some races, and supplying by a new creation others more fitted to occupy the place previously abandoned, is still but the exercise of the same benevolent power. To cause an alteration in those physical circumstances,—to add to the comforts of the newly-created animals,—all these acts imply power of the same order, a perpetual and benevolent superintendence, to take advantage of altered circumstances, for the purpose of producing additional happiness.

But, to have *foreseen*, at the creation of matter and of mind, that a period would

arrive when matter, assuming its prearranged combinations, would become susceptible of the support of vegetable forms; that these should in due time themselves supply the pabulum of animal existence; that successive races of giant forms or of microscopic beings should at appointed periods necessarily rise into existence, and as inevitably yield to decay; and that decay and death—the lot of each individual existence—should also act with equal power on the races which they constitute; that the extinction of every race should be as certain as the death of each individual, and the advent of new genera be as inevitable as the destruction of their predecessors;—to have foreseen all these changes, and to have provided, by one comprehensive law, for all that should ever occur, either to the races themselves, to the individuals of which they are composed, or to the globe which they inhabit, manifests a degree of power and of knowledge of a far higher order.

The vast cycles in the geological changes that have taken place in the earth's surface, of which we have ample evidence, offer another analogy in nature to those mechanical changes of law from which we have endeavoured to extract a *unit* sufficiently large to serve as an imperfect measure for some of the simplest works of the Creator.

The gradual advance of Geology, during the last twenty years, to the dignity of a science, has arisen from the laborious and extensive collection of facts, and from the enlightened spirit in which the inductions founded on those facts have been deduced and discussed. To those who are unacquainted with this science, or indeed to any person not deeply versed in the history of this and kindred subjects, it is impossible to convey a just impression of the nature of that evidence by which a multitude of its conclusions are supported:—evidence in many cases so irresistible, that the records of the past ages, to which it refers, are traced

in language more imperishable than that of the historian of any human transactions ; the relics of those beings, entombed in the strata which myriads of centuries have heaped upon their graves, giving a present evidence of their past existence, with which no human testimony can compete.

It is found that each additional step, in the grouping together of the facts of geology, confirms the view that the changes of our planet, since it has been the abode of man, is but as a page in the massive volumes of its history, every leaf of which, written in the same character, conveys to the decypherer the idea of a succession of the same causes acting with varying intensity, through unequal but enormous periods, each period apparently distinguished by the coming in or going out of new subsidiary laws, yet all submitted to some still higher condition, which has stamped the mark of unity on the series, and points to the conclusion that the minutest changes,

as well as those transitions apparently the most abrupt, have been throughout all time the necessary, the inevitable consequences of some more comprehensive law impressed on matter at the dawn of its existence.

CHAP. III.

ARGUMENT TO SHOW THAT THE DOCTRINES IN
THE PRECEDING CHAPTER DO NOT LEAD TO
FATALISM.

If all the combinations and modifications of matter can be supposed to be traced up to one general and comprehensive law, from which every visible form, both in the organic and inorganic world flows, as the necessary consequence of the first impression of that law upon matter, it might seem to follow that Fate or Necessity governs all things, and that the world around us may not be the result of a contriving mind working for a benevolent purpose.

Such, possibly, may be the first impression

of this view of the subject ; but it is an erroneous view,—one of those, perhaps, through which it is necessary to pass, in order to arrive at truth. Let us, in order to obtain more correct views upon this point, briefly review the labour which the human race has expended, in attaining the limited knowledge we possess. For about six thousand years man has claimed the earth as his heritage, and asserted his dominion over all other beings endued with life ; yet, during a large portion of that period, how small comparatively has been his mental improvement ! Until the invention of printing, the mass of mankind were in many respects almost the creatures of instinct. It is true, the knowledge possessed by each generation, instead of being the gift of Nature, was derived from the instruction of their predecessors ; but, how little were those lessons improved by repeated communication ! Transmitted most frequently by unenlightened instructors, they might lose, but could rarely gain in value.

Before the invention of printing, accidental position determined the opinions and the knowledge of the great mass of mankind. Oral information being almost the only kind accessible, each man shared the opinions of his kindred and neighbours ; and truth, which is ever most quickly and most surely elicited by discussion, lost all those advantages which diversity of opinion always produces for it. The minds of individual men, however powerful, could address themselves only to a very small portion of their fellow men ; their influence was limited by space and restricted by time ; their highest powers were not stimulated into action by the knowledge that their reasonings could have effect where their voices were unheard, by the conviction that the truths which they arrived at, and the discoveries they made, would extend beyond their country and survive their age.

But, since the invention of printing, different has been the position of mankind !

the nature of the instruction no longer depends entirely on the knowledge of the personal instructor. The village schoolmaster communicates to his pupils the power of using an instrument by which not merely the best of their living countrymen, but the greatest and wisest men of all countries and all times, may become their instructors. Even the elementary writings through which this art is taught, give to the pupil, not the sentiments of the teacher, but those which the public opinion of his countrymen esteems most fit for the beginner in knowledge. Thus the united opinions of multitudes of human minds are brought to bear even upon seemingly unimportant points.

If such is the effect of the invention of printing upon ordinary minds, its influence over those more highly endowed is far greater. To them the discussion of the conflicting opinions of different countries and distant ages, and the establishment of new truths, present

a field of boundless and exalted ambition. Advancing beyond the knowledge of their neighbours and countrymen, they may be exposed to those prejudices which result from opinions long stationary ; but encouraged by the approbation of the greatest of other nations, and the more enlightened of their own,—knowing that time alone is wanting to complete the triumph of truth, they may accelerate the approaching dawn of that day which shall pour a flood of light over the darkened intellects of their thankless countrymen—content themselves to exchange the hatred they experience from the honest and the dishonest intolerance of their contemporaries, for that higher homage, alike independent of space and of time, which their memory will for ever receive from the good and the gifted of all countries and all after ages.

Until printing was very generally spread, civilisation scarcely advanced by slow and languid steps ; since this art has become

cheap, its advances have been unparalleled, and its rate of progress vastly accelerated.

It has been stated that the civilisation of the Western World has resulted from its being the seat of the Christian religion : but however much the mild tenor of its doctrines is calculated to assist in producing such an effect, that religion cannot but be injured by an unfounded statement. It is to the easy and cheap methods of communicating thought from man to man, which enable a country to sift, as it were, its whole people, and to produce, in its science, its literature, and its arts, not the brightest efforts of a limited class, but the highest exertions of the most powerful minds among a whole community ;—it is this which has given birth to the wide-spreading civilisation of the present day, and which promises a futurity yet more prolific. Whoever is acquainted with the present state of science and the mechanical arts, and looks back over the inventions and civilisation which the fourteen

centuries subsequent to the introduction of Christianity have produced, and compares them with the advances made during the succeeding four centuries following the invention of printing, will have no doubt as to the effective cause.

It is during these last three or four centuries, that man, considered as a species, has commenced the development of his intellectual faculties—that he has emerged from a position in which he was almost the creature of instinct, to a state in which every step in advance facilitates the progress of his successors. During the first period, arts were discovered by individuals, and lost to the race; in the latter, the diffusion of thought has enabled the reasoning of one class to unite with the observations of another, and the most advanced point of one generation to become the starting post of the next.

It is during this portion of our history that

man has become acquainted with his real position in the universe—that he has measured the distance from that which is to us the great fountain of light and heat—that he has traced the orbits of earth's sister spheres, and calculated the paths of all their dependent worlds—that he has arrived at the knowledge of a law which appears to govern all matter, and whose remotest consequences, if first traced by his telescope, are found to have been written in his theory; or, if first predicted by his theory, are verified by his observations.

Simple as the law of gravity now appears, and beautifully in accordance with all the observations of past and of present times, consider what it has cost of intellectual study. Copernicus, Galileo, Kepler, Euler, Lagrange, Laplace, all the great names which have exalted the character of man, by carrying out trains of reasoning unparalleled in every other science; these, and a host of others, each of

whom might have been the Newton of another field, have all laboured to work out, the consequences which resulted from that single law which *he* discovered. All that the human mind has produced—the brightest in genius, the most persevering in application, has been lavished on the details of the law of gravity.

Had that law been other than it is—had it been, for example, the inverse cube of the distance, it would still have required an equal expense of genius and of labour to have worked out its details. But, between the laws represented by the inverse square, and the inverse cube of the distance, there are interposed an infinite number of other laws, each of which might have been the basis of a system requiring the most extensive knowledge to trace out its consequences. Again, between every law which can be expressed by whole numbers, whether it be direct or inverse, an infinity of others can still be inter-

posed. All these might be combined by two, by three, or in any other groups, and new systems might be imagined,* submitted to such combinations. Thus, another infinity of laws, of a far higher order—in fact, of an *infinitely* higher order—might again be added to the list. And this might still be increased by all the other combinations, of which such laws admit, besides that by addition, to which we have already alluded, thus forming an infinity itself of so high an order, that it is difficult to conceive. Man has, as yet, no proof of the impossibility of the existence of any of these laws. Each might, for any reason we can assign, be the basis of a creation different from our own.

It is at this point that skill and knowledge

* Even beyond this, every law so imagined might be interrupted by any discontinuous function ; and thus be made to agree, for any period, with laws of simpler form, and yet deviate, in one single, or in a certain limited number of cases, and then agree with it for ever.

re-enter the argument, and banish for ever the dominion of chance. The Being who called into existence this creation, of which we are parts, must have *chosen* the present form, the present laws, in preference to the infinitely infinite variety which he might have willed into existence. He must have known and foreseen all, even the remotest consequences of *every one* of those laws, to have penetrated but a little way into *one* of which has *exhausted* the intellect of our whole species.

If such is the view we must take of the knowledge of the Creator, when contemplating the laws of inanimate matter—laws into whose consequences it has cost us such accumulated labour to penetrate—what language can we speak, when we consider that the laws which connect matter with animal life may be as infinitely varied as those which regulate material existence? The little we know, might, perhaps, lead us to infer a far more unlimited field of choice. The chemist has reduced all

the materials of the earth with which we are acquainted, to about fifty simple bodies; but the zoologist can make no such reductions in his science. He claims for one scarcely noticed class — that of intestinal parasites — about thirty thousand species; and, not to mention the larger classes of animals, who shall number the species of infusoria in living waters, still less those which are extinct, and whose scarcely visible relics are contained within the earth, in almost mountain masses.*

In absolute ignorance of any — even the smallest link of those chains which bind life to matter, or that still more miraculous one, which connects mind with both,* we can pursue

* Professor Ehrenberg, of Berlin, has discovered that the tripoli employed in that city for polishing metals, which is dug up at Bilin, in Bohemia, consists almost entirely of the siliceous remains of infusoria, of a species so minute, that about 41,000 millions of them weigh 220 grains, and occupy the space of a cubic inch. The reader will find a translation of the highly interesting papers of Professor Ehrenberg, in the third number of the "Scientific Memoirs," published by Mr. R. Taylor.

our path only by the feeble light of analogy, and humbly hope that the Being, whose power and benevolence are unbounded, may enable us, in some further stage of our existence, to read another page in the history of his mighty works.

Enough, however, and more than enough, may be gathered even from our imperfect acquaintance with matter, and some few of its laws, to prove the unbounded knowledge which must have preceded their organization.

CHAP. IV.

ON THE ACCOUNT OF THE CREATION, IN THE FIRST
CHAPTER OF GENESIS.

A STRANGE and singular argument has frequently been brought against the truth of the facts presented to us by Geology,—facts which every instructed person may confirm by the evidence of his senses. It has been asserted that they cannot be true; because, if admitted, they lead inevitably to the conclusion, that the earth has existed for an enormous period, extending, perhaps, over millions of years; whereas, it was supposed, from the history of the creation as delivered by Moses, that the

earth was first created about six thousand years ago.

A different interpretation has been lately put upon that passage of the sacred writings ; and, according to the highest authorities of the present time, it was not the intention of the writer of the book of Genesis to assign this date to the creation of our globe, but only to that of its most favoured inhabitants.

Now, it is obvious that additional observations, and another advance in science, may at no distant period render necessary another interpretation of the Mosaic narrative ; and this again, at a more remote time, may be superseded by one more in accordance with the existing knowledge of that day. And thus, the authority of Scripture will be gradually undermined by the weak though well-intentioned efforts of its friends in its support. For it is clear that when a work, translated by persons most highly instructed in its language, and seeking,

in plainness and sincerity, to understand its true meaning, admits of such discordant interpretations, it can have little authority as a history of the past, or a guide to the future.

It is time, therefore, to examine this question by another light, and to point out to those who support what is called the literal interpretation of Scripture, the precipice to which their doctrines, if true, would inevitably lead; and to show, not by the glimmerings of elaborate criticism, but by the plainest principles of common sense, that there exists no such fatal collision between the words of Scripture and the facts of nature.

And first, let us examine what must of necessity be the conclusion of any candid mind from the mass of evidence presented to it. Looking solely at the facts in which all capable of investigation agree—facts which it is needless to recite, they having been so fully and ably stated in the works of Mr. Lyell and

Dr. Buckland,—we there see, and with no theoretic eye, the remains of animated beings, more and more differing from existing races, as we descend in the series of strata. Not merely are the petrified bones preserved, displaying marks of the insertion of every muscle necessary for the movement of the living animal, but in some cases we discover even the secretions of their organs, prepared either for nourishment or for defence. Almost every stratum we pause to examine, affords indubitable evidence of having, at some former period, existed for ages at the bottom of some lake or estuary, some inland sea, or some extensive ocean teeming with animal existence, or of having been the surface of a country covered with vegetation, which perished and was renewed at distant and successive periods.

Those, however, who, without the knowledge which enables them to form an opinion on the subject, feel any latent wish that this evidence should be overthrown, would do

well to remember that geology also furnishes strong evidence in favour of the much more direct statement of Moses, as to the recent creation of man. And although we must ever feel a certain degree of caution in admitting negative evidence as conclusive; yet, in the present instance, the fact that the multitude of fossil bones which have been discovered, and which, when examined by persons *duly qualified* for the task, have been uniformly pronounced to be those of various tribes of animals, and not those of the human race, undoubtedly affords strong corroborative evidence in confirmation of the Mosaic account.

In truth, the mass of evidence which combines to prove the great antiquity of the earth itself, is so irresistible, and so unshaken by any opposing facts, that none but those who are alike incapable of observing the facts, and of appreciating the reasoning, can for a moment conceive the present state of its

surface to have been the result of only six thousand years of existence.

What, then, have those accomplished who have restricted the Mosaic account of the creation to that diminutive period, which is, as it were, but a span in the duration of the earth's existence, and who have imprudently rejected the testimony of the senses, when opposed to their philological criticisms? Undoubtedly, if they have succeeded in convincing either themselves or others, that one side of the question must be given up as untenable; those who are so convinced are bound to reject that which rests on testimony, not that which is supported by still existing facts. The very argument which Protestants have opposed to the doctrine of transubstantiation,* would, *if*

* The historian of the "Decline of the Roman Empire," carried the argument yet further;—

"I still remember (he remarks) my solitary transport at the discovery of a philosophical argument against transubstantiation; that the text of Scripture which seems to

their view of the case were correct, be equally irresistible against the book of Genesis.

But let us consider what would be the conclusion of every reasonable being in a parallel case. Let us imagine a manuscript written three thousand years ago, and professing to be a revelation from the Deity, in which it was stated that the colour of the paper of the very book now in the reader's hands is *black*, and that the colour of the ink in the characters which he is now reading is *white*:—with that reasonable doubt of his own individual faculties which would become the inquirer into the truth of a statement said to be derived from so high an origin, he would ask of all those around him, whether to their senses the paper appeared to be *black* and the ink to be *white*. If he found the senses of other individuals agree with his own, then he would undoubt-

“ indicate the real presence is attested only by a single sense—our sight ; while the real presence itself is disproved by three of our senses—the sight, the touch, the taste.”
Gibbon's Memoirs of his Life, vol. i. p. 58.

edly pronounce the alleged revelation a forgery, and those who propounded it to be either deceived or deceivers. He would rightly impute the attempted deceit to moral turpitude, to gross ignorance, or to interested motives in the supporters of it ; but he certainly would not commit the impiety of supposing the Deity to have wrought a miraculous change upon the senses of our whole species, and then to demand their belief in a fact directly opposed to those senses ;—thus throwing doubt upon every conclusion of reason in regard to external objects, and amongst others, upon the very evidence by which the authenticity of that questionable manuscript was itself supported, and even upon the fact of its existence when before their eyes.

Thus, then, had those who attempt to show that the account of the creation, in the book of Genesis, is contradicted by the discoveries of modern science, succeeded, they would have destroyed the testimony of Moses—they would

have uncanonised one portion of Scripture, and by implication have thrown doubt on the remainder. But minds which thus failed to trace out the necessary consequences of their own argument, were not likely to have laid very secure foundations for the basis on which it rested ; and I shall presently prove that the contradiction they have imagined can have no real existence ; and that whilst the testimony of Moses remains unimpeached, we may also be permitted to confide in the testimony of our senses.

CHAP. V.

FURTHER VIEW OF THE SAME SUBJECT.

BEFORE entering on the main argument of the last Chapter, it may be remarked, that the plainest and most natural view of the language employed by the sacred historian is, that his expressions ought to be received by us in the sense in which they were understood by the people to whom he addressed himself. If, when speaking of the creation, instead of using the terms light and water, he had spoken of the former as a wave, and of the latter as the union of two invisible airs, he would assuredly have been perfectly unintelligible to his country-

men:—at the distance of above three thousand years his writings would just have begun to be comprehended ; and possibly three thousand years hence those views may be as inapplicable to the then existing state of human knowledge as they would have been when the first chapter of Genesis was written.

Those, however, who attempt to disprove the facts presented By observation, by placing them in opposition to revelation, have mistaken the very groundwork of the question. The revelation of Moses itself rests, and must necessarily rest, on *testimony*. Moses, the author of the oldest of the sacred books, lived about fifteen hundred years before the christian era, or about three thousand three hundred years ago. The oldest manuscripts of the Pentateuch at present known, appear to have been written about 900 years ago.* These were copied from

* Mr. Horne, in the *Introduction to the Critical Study of the Holy Scriptures*, states, that the total number of Hebrew MSS. collated by Dr. Kennicott, for his critical

others of older date, and those again might probably, if their history were known, be traced up through a few transcripts to the original author; but no part of this history is revelation; it is testimony. Although the matter

edition of the Hebrew Bible, was about 630. In that work, Mr. Horne gives an account of ten of the most ancient of these MSS.: four of which contain the first chapter of Genesis, viz. :—

No. 4. Codex Cæsenaë, in the Malatesta Library at Bologna, written about the end of the eleventh century.

No. 6. Codex Mediolanensis, written towards the close of the twelfth century. “The beginning of the book of Genesis, and the end of Leviticus and Deuteronomy, have been written by a later hand.”

No. 8. Codex Parisiensis, 27, about the commencement of the twelfth century.

No. 10. Codex Parisiensis, 24, written at the beginning of the twelfth century.

In the same work is an account of six of the most ancient of four hundred and seventy-nine MSS. collated by M. De Rossi. Two of these contain the first chapter of Genesis; and the date of both is about the end of the eleventh or beginning of the twelfth century.

Of the Manuscripts of the Samaritan versions of the Pentateuch, cited in the same work,—one is the Codex 197, in the Ambrosian Library at Milan, which in the opinion of Dr. Kennicott is certainly not later than the tenth century.

which the book contains was revealed to Moses, the fact that what we now receive as revelation is the same with that originally communicated revelation, is entirely dependent on testimony.

Admitting, however, the full weight of that evidence above mentioned, corroborated as it is by the Samaritan version ; nay, even supposing that we now possessed the identical autograph of the book of Genesis by the hand of its author, a most important question remains,—What means do we possess of translating it ?

In similar cases we avail ourselves of the works of the immediate predecessors, and of the contemporaries of the writer ; but here we are acquainted with no work of any predecessor, — with no writing of any contemporary ; nor do we possess the works of any writers in the same language, even during several succeeding centuries, if we except some few of the sacred books. How, then, is it

possible to satisfy our minds of the minute shades of meaning of words, perhaps employed popularly; or, if they were employed in a stricter and more philosophical sense, where are the contemporary philosophical writings from which their accurate interpretation may be gained?

The extreme difficulty of such an inquiry will be made apparent by imagining a parallel case. Let us suppose all writings in the English, and indeed in all other languages previous to the time of Shakespeare, to have been destroyed;—let us imagine one manuscript of his plays to remain, but not a vestige of the works of any of his contemporaries; and further, suppose the whole of the succeeding works of English literature to be annihilated nearly up to the present time. Under such circumstances, what would be our knowledge of Shakespeare? We should undoubtedly understand the general tenor and the plots of his plays. We should *read* the language of all his characters;

and viewing it generally, we might even be said to understand it. But how many words connected with the customs, habits, and manners of the time must, under such circumstances, necessarily remain unknown to us! Still further, if any question arose, requiring for its solution a knowledge of the minute shades of meaning of words now long obsolete, or of terms supposed to be used in a strict or philosophical sense, how completely unsatisfactory must our conclusions remain! Such I conceive to be the view which common sense bids us take of the interpretation of the book of Genesis. The language of the Hebrews, in times long subsequent to the date of that book, may not have so far changed as to prevent us from understanding generally the history it narrates; but there appears to be no reasonable ground for venturing to pronounce with confidence on the minute shades of meaning of allied words, and on such foundations to support an argument opposed to the evidence of our senses.

I should have hesitated in offering these remarks respecting the right interpretation of the Mosaic account of the creation, had my argument depended on any acquaintance with the language in which the sacred volume is written, or on any refinements of criticism, had I possessed that knowledge; but in estimating its validity, or in supplying a more cogent argument, I intreat the reader to consider well the difficulties which it is necessary to meet.

1st. The Church of England, if we may judge by the writings of those placed in authority, has hitherto considered it to have been expressly stated in the book of Genesis, that the earth was *created* about six thousand years ago.

2dly. Those observers and philosophers who have spent their lives in the study of Geology, have arrived at the conclusion that there exists irresistible evidence, that the date

of the earth's first formation is far anterior to the epoch supposed to be assigned to it by Moses; and it is now admitted by all competent persons, that the formation even of those strata which are nearest the surface must have occupied vast periods—probably millions of years—in arriving at their present state.

3dly. Many of the most distinguished members of the Church of England now distinctly and formally admit the fact of such a lengthened existence of the earth we inhabit. It is so stated in the eighth *Bridgewater Treatise*, a work written by the Professor of Geology in the University of Oxford—himself holding an office of dignity in that Church, and expressly appointed to write upon that subject, by the Archbishop of Canterbury, and the Bishop of London.

4thly. The Professor of Hebrew at the same University has proposed a new interpretation of those passages in the Book of Genesis,

which were hitherto supposed to be adverse to the now admitted facts.

Such being the present state of the case ;— it surely becomes a duty to require a very high degree of evidence, before we again claim authority for the opinion that the book of Genesis contains such a precise account of the work of the creation, that we may venture to appeal to it as a refutation of observed facts. The history of the past errors of our parent Church supplies us with a lesson of caution which ought not to be lost by its reformed successors. The fact that the venerable Galileo was compelled publicly to deny, on bended knee, a truth of which he had the most convincing demonstration, remains as a beacon to all after time, and ought not to be without its influence on the inquiring minds of the present day.

If the explanation offered by the Professor of Hebrew be admitted, those who adhere to it must still have some misgivings

as to the probability that new discoveries in nature may give continual occasion for amended translations of various texts; whereas, should the view which has been advocated in this chapter be found correct, instead of fearing that the future progress of science may raise additional difficulties in the way of revealed religion, we are at once relieved from all doubt on that subject.

CHAP. VI.

OF THE DESIRE OF IMMORTALITY.

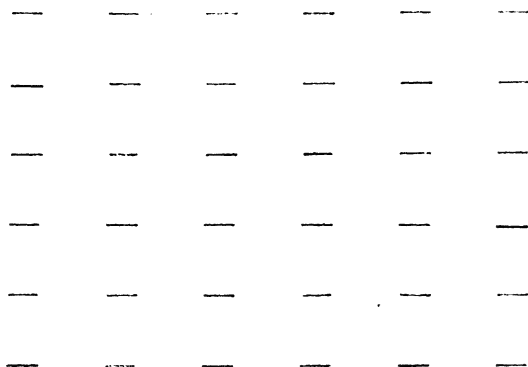

THE wish universally felt, and expressed in every variety of form, to remain in the memory of our fellow-creatures after our passage from the present scene, has rightly been adduced as an intimation of the desire of immortality, and has sometimes been explained as being founded on an instinctive belief that we are destined to be immortal by the Creator.

The hope of remaining embalmed in the fond recollection of those we held most dear in life, and even of being remembered by our

more immediate descendants, has something in it nearly connected with self; but the wish for more extended reputation,—the desire that our name should pass in after times from mouth to mouth, cherished and admired by those whose applause is won by no personal recollections: or the still more fervent aspirations, that we may stamp indelibly on the age we live in some mark of our individual existence which shall form an epoch in the history of man: these hopes, these longings, receive no interpretation from the all-dominant principle of *self*; unless indeed we suppose the sentient principle of our nature not merely to exist, but also to be conscious of, and gratified by, the earthly immortality it had achieved. Yet the more distant and the higher the objects we pursue, the less is it possible to suppose the mind, so occupied on earth, can, in another stage of its existence, derive pleasure from such perceptions.

To support this opinion, it is only necessary

to examine the states of mind in the various classes of the aspirants after fame.

Through every form of society, and through every rank of each, may be traced this universal passion. Examine the most highly civilized inhabitants of earth ; search through it for the most cultivated and refined in taste ; for the most sagacious in penetrating the passions of mankind, the most skilful in wielding them, or the most powerful in intellectual might. Taste, feeling, passion, ambition, genius, severed or combined, equally yield

obedience to its sway, and present, under different appearances, the effects of its all-controlling power.

Look at the highest productions of the poet or the novelist. By connecting his story with the scenery, the traditions, or the history of his country, he may ensure for it a local interest, a domestic and transitory popularity ; but it is that deeper penetration into the secrets of the human heart, which enables him to select from amongst the same materials, those feelings that are common to the race which have, as occasion called them forth, appeared, and will continue to reappear, as long as the same affections and passions shall continue to animate and agitate our frames.

From the examination of these its highest forms, we may gather some common principles, and be enabled to perceive that the love of fame is far different from that passion for vulgar applause with which it is too frequently confounded. We may learn, that the higher the intellectual powers devoted to the task, the more remote the period for which ambition delights to raise its far distant altar.

CHAP. VII.

ON TIME.

—	—	—	—	—	—
—	—	—	—	—	—
—	—	—	—	—	—
—	—	—	—	—	—
—	—	—	—	—	—

TIME and change are great, only with reference to the faculties of the beings which note them. The insect of an hour, fluttering, during its transient existence, in an atmosphere of perfume, would attribute unchanging duration to the beautiful flowers of the cistus, whose petals cover the dewy

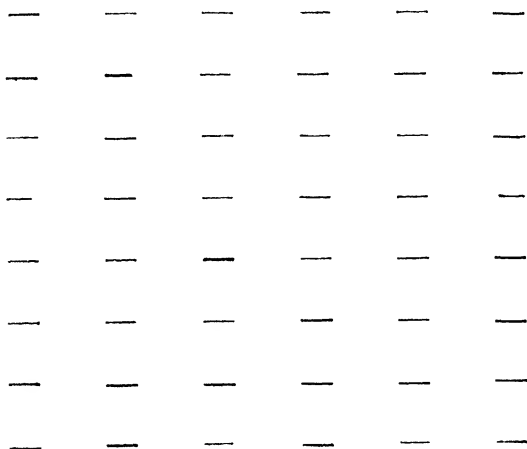

grass but a few hours after it has received the lifeless body of the gnat. These flowers, could they reflect, might contrast their transitory lives with the prolonged existence of their greener neighbours. The leaves themselves, counting their brief span by the lapse of a few moons, might regard as almost indefinitely extended the duration of the common parent of both leaf and flower. The lives of individual trees are lost in the continued destruction and renovation which take place in forest masses. Forests themselves, starved by the exhaustion of the soil, or consumed by fire, succeed each other in slow gradation. A forest of oaks waves its luxuriant branches over a spot which has been fertilized by the ashes of a forest of pines. These periods again merge into other and still longer cycles, during which the latest of a thousand forests sinks beneath the waves, from the gradual subsidence of its parent earth ; or in which extensive inundations, by accumulating the silt of centuries, gradually convert the

living trunks into their stony resemblances. Stratum upon stratum subsides in comminuted particles, and is accumulated in the depths of ocean, whence they again arise, consolidated by pressure and by heat, to form the continents and mountains of a new creation.

Such, in endless succession, is the history of the changes of the globe we dwell upon ; and human observation, aided by human reason, has as yet discovered few signs of a beginning—no symptom of an end. Yet, in that more extended view which recognises our planet as one amongst the attendants of a central luminary ; that sun itself,—the soul, as it were, of vegetable and animal existence, but an insignificant individual among its congeners of the milky way:—when we remember that that cloud of light, gleaming with its myriad systems, is but an isolated nebula amongst a countless host of rivals, which the starry firmament surrounding us

on all sides, presents in every varied form ;—some as uncondensed masses of attenuated light ;—some as having, in obedience to attractive forces, assumed a spherical figure ; others, as if farther advanced in the history of their fate, enclosing a denser central nucleus surrounded by a more diluted light, spreading into such vast space, that the whole of our own nebula would be lost in it :—others there are, in which the apparently unformed and irregular mass of nebulous light is just curdling, as it were, into separate systems ; whilst many present a congeries of distinct points of light, each, perhaps, the splendid luminary of a creation more glorious than our own ;—when the birth, the progress, and the history of sidereal systems are considered, we require some other unit of time than even that comprehensive one which astronomy has unfolded to our view. Minute and almost infinitesimal as is the time which comprises the history of our race compared with that which records the history of our system, the space even of

this latter period forms too limited a standard wherewith to measure the footmarks of eternity.

CHAP. VIII.

ARGUMENT FROM LAWS INTERMITTING ON THE
NATURE OF MIRACLES.*

THE object of the present chapter is to show that it is more consistent with the attributes of the Deity to look upon miracles not as deviations from the laws assigned by the Almighty for the government of matter and of mind ; but as the exact fulfilment of much more extensive laws than those we suppose to exist. In fact, if we were endued with acuter senses and higher reasoning faculties, they are the very points we should seek to observe, as the tests of any hypothesis we had been led to frame concerning the nature of

* See Note D in Appendix.

those laws. Even with our present imperfect faculties we frequently arrive at the highest confirmation of our views of the laws of nature, by tracing their action under *singular* circumstances.

The mode by which I propose to arrive at these conclusions is, by again appealing to the judgment which each individual will himself form, when examining that piece of mere human mechanism, to which the argument so frequently compels me to advert. If he agrees with me, that the second of the two views presented to him exhibits a higher degree of knowledge, and a higher exertion of power, than the first, he must inevitably conclude, that the view here suggested of the nature of miracles, assigns a far higher degree of knowledge and power to the Deity.

Let the reader suppose himself placed before the calculating engine, and let him again observe and ascertain, by lengthened

induction, the nature of the law it is computing. Let him imagine that he has seen the changes wrought on its face during the lapse of thousands of years, and that, without one solitary exception, he has found the engine register the series of square numbers. Suppose, now, the maker of that machine to say to the observer, “ I will, by moving a certain mechanism, which is invisible to you, cause the engine to make one cube number instead of a square, and then to revert to its former course of square numbers;” the observer would be inclined to attribute to him a degree of power but little superior to that which was necessary to form the original engine.*

But, let the same observer, after the same lapse of time—the same amount of uninterrupted experience of the uniformity of the law of square numbers, hear the maker of the engine say to him—“ The next number which shall appear on those wheels, and which you expect to find a square number, shall

“ not be so. When the machine was originally ordered to make these calculations, I impressed on it a law, which should coincide with that of square numbers in every case, *except* the one which is now about to appear ; after which no future exception can ever occur, but the unvarying law of the squares shall be pursued until the machine itself perishes from decay.”

Undoubtedly the observer would ascribe a greater degree of power to the artist who had thus willed that event which he foretells at the distance of ages before its arrival.

If the contriver of the engine then explain to him, that, by the very structure of it, he has power to order *any* number of such apparent deviations from its laws to occur at any future periods, however remote, and that each of these may be of a different kind ; and, if he also inform him, that he gave it that structure in order to meet events, which he foresaw must

happen at those respective periods, there can be no doubt that the observer would ascribe to the inventor far higher knowledge than if, when those events severally occurred, he were to intervene, and temporarily to alter the calculations of the machine.

If, besides this, the contriver were so far to explain the structure of the engine that the observer could himself, by some simple process, such as the mere moving of a bolt, call into action those apparent deviations whenever certain combinations were presented to his eye; if he were thus to impart a power of predicting such excepted cases, dependent on the will, though in other respects beyond the limits of the observer's power and knowledge, —such a structure would be admitted as evidence of a still more skilful contrivance.

The engine which, in a former chapter, I introduced to the reader, possesses these powers. It may be set, so as to obey any

given law; and, at any periods, however remote, to make one or more *seeming* exceptions to that law. It is, however, to be observed, that the *apparent* law which the spectator arrived at, by an almost unlimited induction, is not the full expression of the law by which the machine acts; and that the excepted case is as absolutely and irresistibly the necessary consequence of its primitive adjustment, as is any individual calculation amongst the countless multitude which it may previously have produced.

When the construction of that engine was first attempted, I did not seek to give to it the power of making calculations so far beyond the reach of mathematical analysis as these appear to be; nor can I now foresee a probable period at which they may become practically available to human purposes. I had determined to invest the invention with a degree of generality which should include a wide range of mathematical power; and I was

well aware that the mechanical generalisations I had organised contained within them much more than I had leisure to study, and some things which will probably remain unproductive to a far distant day.

Amongst those combinations which I was afterwards induced to examine, I observed the powers I have now recorded ; and the reflections they produced in my own mind, impelled me to pursue them for a time. If the reader agrees with me in opinion, that these speculations lead to a more exalted view of the great Author of the universe than any we have hitherto possessed, he must also have arrived at the conclusion, that the study of the most abstract branch of practical mechanics, combined with that of the most abstruse portions of mathematical science, has no tendency to incapacitate the human mind from the perception of the evidences of natural religion ; and that even those very sources themselves may furnish arguments which open views of the grandeur of creation

perhaps more extensive than any which the sciences of observation or of physics have yet supplied.

It may not, perhaps, be without its use to suggest another illustration derived from the same quarter respecting the nature of miracles. It is known that mathematical laws are sometimes expressed by curves. The figure 1 (p. 101) represents a re-entering curve of four dimensions, whose law of formation is given in the note.* A slight change in the nature of the constants makes it assume the form of fig. 2, which is still a continuous curve; but a further change of the constants causes it to have two ovals, quite disconnected from the larger portion; and, as the constants again alter, these ovals are reduced to points.

* The equation

$$y^4 - 4y^2 = -ax^4 + bx^3 + cx^2 + dx + e$$

expresses several figures of an oval form, according to the nature of the roots of the equation,

$$-ax^4 + bx^3 + cx^2 + dx + e = 0.$$

If its two lesser roots become imaginary, the curves, figures 1, 2, 3, are produced.

In all four cases, every point in each branch of the curve obeys the same general law. The points, P and Q, though strictly invisible to the eye, are yet detected by mathematical analysis, and fulfil as precisely the original equation as any of the infinite number of other points, which constitute the rest of the curve. These points might be situated on the curve itself, and they are well known to mathematicians. It is to these *singular points*, which really fulfil the law of the curve, but which present to those who judge of them only by the organ of sight an apparent discontinuity, that I wish to call the attention, as offering an illustration of the doctrine here explained respecting miracles.

It has been remarked, in the beginning of the present chapter, that it is to the singular points—to those points of such infinitely rare occurrence in a curve—that we frequently have recourse, as the test of our theories, for explaining the phenomena of nature.

Fig. 4.

The existence of conical refraction in certain crystals, under peculiar circumstances, was predicted by Sir W. Hamilton ; and, from an analytical investigation into the nature of the curve surface, which represents the form of the luminiferous wave within the crystal, he ascertained that it had four conoidal cusps, at each of which there were, consequently, an infinite number of tangent planes. The course of the refracted ray being determined by the tangent plane to the wave surface, it followed that a single ray within the crystal, transmitted in the direction of the line joining two opposite cusps, corresponded to an infinite number of refracted rays without, constituting a refracted cone.

A second case of conical refraction, predicted by Sir William Hamilton, depended on another mathematical fact—namely, that the wave surface is touched in an infinite number of points, constituting a small circle of contact, by a single plane parallel to one of the circular sections of the surface of elasticity.

Professor Lloyd undertook to make the very delicate experiments required for this most interesting investigation. Of its great importance he was fully aware, for he remarks—

“ Here, then, are two singular and unexpected consequences of the undulatory theory, not only unsupported by any facts hitherto observed, but even opposed to all the analogies derived from experience. If confirmed by experiment, they would furnish new and almost convincing proofs of that theory; and, if disproved, on the other hand, it is evident that the theory must be abandoned or modified.*

On examining the first of these cases, experimentally, the fact of conical refraction was fully established. But a new result now presented itself: the rays of light thus conically

* Trans. of Royal Irish Academy, Vol. XVII.

refracted were found to be polarized ; and it was observed, that “ the angle between the
“ planes of polarization of any two rays of
“ the cone was half the angle between the
“ planes, containing the rays themselves, and
“ the axis.”

This new law, thus approximately obtained by experiment, led the observer back to the theory ; and, on a further examination, he detected in that theory the very law he had just discovered by observation.

The second case of conical refraction required experiments of a still more delicate nature. They were, however, made, and succeeded equally. The conically refracted ray was found to be polarised, according to the law which, in this instance, analysis had predicted ; and, to complete the triumph of this union of theory and experiment, the measures in both cases, when made under proper circumstances, accorded with the theoretical conclusions,

within such limits as might be fairly attributed to the unavoidable errors of observation.

It is worthy of remark, that, at first, two facts presented themselves, which seemed to be at variance with the theory. In the first place, the emergent rays formed a solid cone, instead of a conical surface; and, in the second place, the calculated angle, subtended by the sides of the cone, was only one half the observed angle. Both the facts were shown to depend upon the *size* of the aperture through which the light was admitted, and to arise from the rays which were inclined at small angles to the single theoretical direction. When the aperture was diminished, so as to be *very* small, (the case calculated by Sir William Hamilton,) then the cone of light became truly a conical surface, and the observed angle was the same as the calculated one.*

* Those who are acquainted with the history of astronomy, cannot fail to recall a parallel discrepancy between observation and calculation in the theory of gravity. It appeared

to result from that law, that the motion of the moon's apogee was only one half of what observation proved it to be ; and it is singular that Euler, D'Alembert, and Clairaut arrived, by different methods, at the same erroneous result ; and the truth of the great law of gravity appeared for a time to be doubtful. Clairaut, however, having assumed that the law of gravity contained a term sensible only at small distances (such as that of the moon), re-calculated the question, and finding it necessary, in consequence of the existence of this term, to push his approximation further than he had done, arrived at the conclusion, that the co-efficient of the new term vanished ; and also, that when the approximations were sufficiently pursued, the simple law of the inverse square of the distance accounted for the whole of the motions which observations had discovered.

CHAP. IX.

ON THE PERMANENT IMPRESSION OF OUR WORDS
AND ACTIONS ON THE GLOBE WE INHABIT.

THE principle of the equality of action and reaction, when traced through all its consequences, opens views which will appear to many persons most unexpected.

The pulsations of the air, once set in motion by the human voice, cease not to exist with the sounds to which they gave rise. Strong and audible as they may be in the immediate neighbourhood of the speaker, and at the immediate moment of utterance, their quickly

attenuated force soon becomes inaudible to human ears. The motions they have impressed on the particles of one portion of our atmosphere, are communicated to constantly increasing numbers, but the total quantity of motion measured in the same direction receives no addition. Each atom loses as much as it gives, and regains again from other atoms a portion of those motions which they in turn give up.

The waves of air thus raised, perambulate the earth and ocean's surface, and in less than twenty hours every atom of its atmosphere takes up the altered movement due to that infinitesimal portion of the primitive motion which has been conveyed to it through countless channels, and which must continue to influence its path throughout its future existence.*

* La courbe décrite par une simple molécule d'air ou vapeurs est réglée d'une manière aussi certain que les orbites planétaires : il n'y a de différence entre elles, que

But these aerial pulses, unseen by the keenest eye, unheard by the acutest ear, unperceived by human senses, are yet demonstrated to exist by human reason ; and, in some few and limited instances, by calling to our aid the most refined and comprehensive instrument of human thought, their courses are traced and their intensities are measured. If man enjoyed a larger command over mathematical analysis, his knowledge of these motions would be more extensive ; but a being possessed of unbounded knowledge of that science, could trace every the minutest consequence of that primary impulse. Such a being, however far exalted above our race, would still be immeasurably below even our conception of infinite intelligence.

But supposing the original conditions of each atom of the earth's atmosphere, as well as all the extraneous causes acting on it to be

celle qu'y met notre ignorance.—*La Place, Théorie Analytique des Probabilités.* Int. p. iv.

given, and supposing also the interference of no new causes, such a being would be able clearly to trace its future but inevitable path, and he would distinctly foresee and might absolutely predict for any, even the remotest period of time,* the circumstances and future history of every particle of that atmosphere.

Let us imagine a being, invested with such knowledge, to examine at a distant epoch the coincidence of the facts with those which his profound analysis had enabled him to predict. If any the slightest deviation existed, he would immediately read in its existence the action of a new cause; and, through the aid of the same analysis, tracing this discordance back to its source, he would become aware of the time of its commencement, and the point of space at which it originated.

Thus considered, what a strange chaos is this wide atmosphere we breathe! Every

* See Note C in the Appendix.

atom, impressed with good and with ill, retains at once the motions which philosophers and sages have imparted to it, mixed and combined in ten thousand ways with all that is worthless and base. The air itself is one vast library, on whose pages are for ever written all that man has ever said or woman whispered. There, in their mutable but unerring characters, mixed with the earliest, as well as with the latest sighs of mortality, stand for ever recorded, vows unredeemed, promises unfulfilled, perpetuating in the united movements of each particle, the testimony of man's changeful will.

But if the air we breathe is the never-failing historian of the sentiments we have uttered, earth, air, and ocean, are the eternal witnesses of the acts we have done. The same principle of the equality of action and reaction applies to them: whatever movement is communicated to any of their particles, is transmitted to all around it, the share of each being

diminished by their number, and depending jointly on the number and position of those acted upon by the original source of disturbance. The waves of air, although in many instances perceptible to the organs of hearing, are only rendered visible to the eye by peculiar contrivances; but those of water offer to the sense of sight the most beautiful illustration of transmitted motion. Every one who has thrown a pebble into the still waters of a sheltered pool, has seen the circles it has raised gradually expanding in size, and as uniformly diminishing in distinctness. He may have observed the reflection of those waves from the edges of the pool. He may have noticed also the perfect distinctness with which two, three, or more series of waves each pursues its own unimpeded course, when diverging from two, three, or more centres of disturbance. He may have seen, that in such cases the particles of water where the waves intersect each other, partake of the movements due to each series.

No motion impressed by natural causes, or by human agency, is ever obliterated. The ripple on the ocean's surface caused by a gentle breeze, or the still water which marks the more immediate track of a ponderous vessel gliding with scarcely expanded sails over its bosom, are equally indelible. The momentary waves raised by the passing breeze, apparently born but to die on the spot which saw their birth, leave behind them an endless progeny, which, reviving with diminished energy in other seas, visiting a thousand shores, reflected from each and perhaps again partially concentrated, will pursue their ceaseless course till ocean be itself annihilated.

The track of every canoe, of every vessel which has yet disturbed the surface of the ocean, whether impelled by manual force or elemental power, remains for ever registered in the future movement of all succeeding particles which may occupy its place. The furrow which it left is, indeed, instantly filled up by

the closing waters ; but they draw after them other and larger portions of the surrounding element, and these again once moved, communicate motion to others in endless succession.

The solid substance of the globe itself, whether we regard the minutest movement of the soft clay which receives its impression from the foot of animals, or the concussion arising from the fall of mountains rent by earthquakes, equally communicates and retains, through all its countless atoms, their apportioned shares of the motions so impressed.

Whilst the atmosphere we breathe is the ever-living witness of the sentiments we have uttered, the waters, and the more solid materials of the globe, bear equally enduring testimony of the acts we have committed.

If the Almighty stamped on the brow of the earliest murderer,—the indelible and visible

mark of his guilt,—he has also established laws by which every succeeding criminal is not less irrevocably chained to the testimony of his crime; for every atom of his mortal frame, through whatever changes its severed particles may migrate, will still retain, adhering to it through every combination, some movement derived from that very muscular effort, by which the crime itself was perpetrated.

The soul of the negro, whose fettered body surviving the living charnel-house of his infected prison, was thrown into the sea to lighten the ship, that his christian master might escape the limited justice at length assigned by civilized man to crimes whose profit had long gilded their atrocity,—will need, at the last great day of human account, no living witness of his earthly agony.* When

* The following extract is from a report by Captain Hayes to the Admiralty, of a representation made to him respecting one of these vessels in 1832.

“ The master having a large cargo of these human beings

man and all his race shall have disappeared from the face of our planet, ask every particle

chained together, with more humanity than his fellows, permitted some of them to come on deck, *but still chained together*, for the benefit of the air; when they immediately commenced jumping overboard, hand in hand, and drowning in couples; and, continued the person (relating the circumstance), 'without any cause whatever.' Now, these people were just brought from a situation between decks, and to which they knew they must return, where the scalding perspiration was running from one to the other, covered also with their own filth, and where *it is no uncommon occurrence for women to be bringing forth children, and men dying at their side*, with full in their view *living and dead bodies chained together*; and the living, in addition to all their other torments, labouring under the most famishing thirst (being in very few instances allowed more than a pint of water a day);—and, let it not be forgotten, that these unfortunate people had just been torn from their country, their families, their all! Men dragged from their wives, women from their husbands and children, girls from their mothers, and boys from their fathers; and yet in this man's eye (for heart and soul he could have had none) there was no cause whatever for jumping overboard and drowning. This, in truth, is a rough picture; but it is not highly coloured. *The men are chained in pairs*; and, as a proof they are intended so to remain to the end of the voyage, *their fetters are not locked, but rivetted by the blacksmith*, and as deaths are frequently occurring *living men*

of air still floating over the unpeopled earth, and it will record the cruel mandate of the tyrant. Interrogate every wave which breaks unimpeded on ten thousand desolate shores, and it will give evidence of the last gurgle of the waters which closed over the head of his

are often for a length of time confined to dead bodies ; the living man cannot be released till the blacksmith has performed the operation of cutting the clench of the rivet with his chisel ; and I have now an officer on board the Dryad, who, on examining one of these slave vessels, found not only living men chained to dead bodies, but the latter in a putrid state. And we have now a case reported here, which, if true, is too horrible and disgusting to be described."—*Parliamentary Paper*, 1832, B, pp. 170, 171, as quoted in the *Quarterly Review*, Dec. 1835.

When the ink was scarcely dry on the paper on which the remarks in the text, suggested by a former description of the atrocities of the slave trade, was written, the following paragraph caught my attention :

"SLAVE TRADE.—His Majesty's ship *Thalia*, 31, Captain R. Wauchope, has captured on the coast of Africa, two slave vessels—one the *Félicité*, 611 slaves ; the other, the *Adalia*, with 409 slaves. It appears the latter vessel had been chased by the boats of one of our cruisers, and to avoid being come up with she threw overboard upwards of 150 of the poor wretches who were on board, besides almost all her heavy stores."—*Western Luminary*, May 1837.

dying victim : confront the murderer with every corporeal atom of his immolated slave, and in its still quivering movements he will read the prophet's denunciation of the prophet king.*

* " And Nathan said unto David—*Thou art the man.*"

CHAP. X.

ON HUME'S ARGUMENT AGAINST MIRACLES.

FEW arguments have excited greater attention, and produced more attempts at refutation, than the celebrated one of David Hume, respecting miracles; and it might be added, that more sophistry has been advanced against it, than its author employed in the whole of his writings.

It must be admitted that in the argument, as originally developed by its author, there exists some confusion between personal experience and that which is derived from testimony; and that there are several other points open to criticism and objection; but the main argu-

ment, divested of its less important adjuncts, never has, and never will be refuted. Dr. Johnson seems to have been of this opinion, as the following extract from his life by Boswell proves :—

“ Talking of Dr. Johnson’s unwillingness to believe extraordinary things, I ventured to say—

“ ‘ Sir, you come near to Hume’s argument against miracles—That it is more probable witnesses should lie, or be mistaken, than that they should happen.’

“ Johnson.—‘ Why, Sir, Hume, taking the proposition simply, is right. But the Christian revelation is not proved by miracles alone, but as connected with prophecies, and with the doctrines in confirmation of which miracles were wrought.’ ”*

Hume contends that a miracle is a violation of the laws of nature; and as a firm and unalterable experience has established these laws, the proof against a miracle from the very nature of the fact, is as entire as any argument from experience can possibly be imagined.

* Boswell’s Life of Johnson. Oxford, 1826. vol. iii. p. 169.

“ The plain consequence is (and it is a general maxim
“ worthy of our attention), that no testimony is sufficient
“ to establish a miracle, unless the testimony be of such a
“ kind, that its falsehood would be more miraculous than the
“ fact which it endeavours to establish : and even in that case
“ there is a mutual destruction of arguments, and the superior
“ only gives us an assurance suitable to that degree of force
“ which remains after deducting the inferior.” *

The word *miraculous* employed in this passage is evidently equivalent to *improbable*, although the improbability is of a very high degree.

The condition, therefore, which, it is asserted by the argument of Hume, must be fulfilled with regard to the testimony, is that the *improbability* of its falsehood must be GREATER than the *improbability* of the occurrence of the fact.

This is a condition which, when the terms in which it is expressed are understood, immediately commands our assent. It is in the

* Hume's Essays, Edinburgh, 1817, vol. ii. p. 117.

subsequent stage of the reasoning that the fallacy is introduced. Hume asserts, that this condition cannot be fulfilled by the evidence of *any number* of witnesses, because our experience of the truth of human testimony is not uniform and without any exceptions ; whereas, our experience of the course of nature, or our experience against miracles, is uniform and uninterrupted.

The only sound way of trying the validity of this assertion is to *measure* the numerical value of the two improbabilities, one of which it is admitted must be greater than the other ; and to ascertain whether, by making any hypothesis respecting the veracity of each witness, it is possible to fulfil that condition by any finite number of such witnesses.

Hume appears to have been but very slightly acquainted with the doctrine of probabilities, and, indeed, at the period when he wrote, the details by which the conclusions

he had arrived at could be proved or refuted were yet to be examined and arranged. It is, however, remarkable that the opinion he maintained respecting our knowledge of causation is one which eminently brings the whole question within the province of the calculus of probabilities. In fact, its solution can only be *completely* understood by those who are acquainted with that most difficult branch of science. By those who are not so prepared, certain calculations, which will be found more fully developed in the Note (E), must be taken for granted; and all that can be attempted will be, to convey to them a general outline of the nature of the principles on which these enquiries depend.

A miracle is, according to Hume, an event which has never happened within the experience of the whole human race. Now, the improbability of the future happening of such an occurrence may be calculated according to two different views.

We may conceive an urn, containing *only* black and white balls, from which m black balls have been successively drawn and replaced, one by one; and we may calculate the probability of the appearance of a white ball at the next drawing. This would be analogous to the case of one human being raised from the dead after m instances to the contrary.

Looking, in another point of view, at a miracle, we may imagine an urn to contain a very large number of tickets, on each of which is written one of the series of natural numbers. These being thoroughly mixed together, a single ticket is drawn: the prediction of the particular number inscribed on the ticket about to be drawn may be assimilated to the occurrence of a miracle.

According to either of these views, the probability of the occurrence of such an event by mere accident may be calculated. Now, the reply to Hume's argument is this: Admit-

ting at once the essential point, viz. that the improbability of the concurrence of the witnesses in falsehood must be *greater* than the improbability of the miracle, it may be denied that this does not take place. Hume has asserted that, in order to prove a miracle, a certain improbability must be *greater* than another; and he has also asserted that this *never* can take place.

Now, as each improbability can be truly measured by number, the *only* way to refute Hume's argument is by examining the *magnitude* of these numbers. This examination depends on known and admitted principles, for which the reader, who is prepared by previous study, may refer to the work of Laplace, *Théorie Analytique des Probabilités*; Poisson, *Recherches sur la Probabilité des Jugements*, 1837; or he may consult the article *Probabilities*, by Mr. De Morgan, in the *Encyclopædia Metropolitana*, in which he will find this subject examined.

One of the most important principles on which the question rests, is the concurrence of the testimony of independent witnesses. This principle has been stated by Campbell, and has been employed by the Archbishop of Dublin,* and also by Dr. Chalmers.† It requires however to be combined with another principle, in order to obtain the numerical values of the quantities spoken of in the argument. The following example may be sufficient for a popular illustration.

Let us suppose that there are witnesses who will speak the truth, and who are not themselves deceived in ninety-nine cases out of a hundred. Now, let us examine what is the probability of the falsehood of a statement about to be made by two such persons absolutely unknown to and unconnected with each other.

Since the order in which independent wit-

* *Elements of Rhetoric*, by R. Whately, D.D. p. 57, 1832.

† *Evidence of Christian Revelation*, vol. i. p. 129.

nesses give their testimony does not affect their credit, we may suppose that, in a given number of statements, both witnesses tell the truth in the ninety-nine first cases, and the falsehood in the hundredth.

Then the first time the second witness B testifies, he will agree with the testimony of the first witness A, in the ninety-nine first cases, and differ from him in the hundredth. Similarly, in the second testimony of B, he will again agree with A in ninety-nine cases, and differ in the hundredth, and so on for ninety-nine times; so that, after A has testified a hundred, and B ninety-nine times, we shall have

99 \times 99 cases in which both agree,

99 cases in which they differ, A being wrong.

Now, in the hundredth case in which B testifies, he is wrong; and, if we combine this with the testimony of A, we have ninety-nine cases in which A will be right and B wrong; and one case only in which both A and B will

agree in error. The whole number of cases, which amounts to ten thousand, may be thus divided :—

$99 \times 99 =$	9801 cases in which A and B agree in truth,
$1 \times 99 =$	99 cases in which B is true and A false,
$99 \times 1 =$	99 cases in which A is true and B false,
$1 \times 1 =$	1 case in which both A and B agree in a
	falsehood.
<hr/>	
	10,000 cases.

As there is only one case in ten thousand in which two such independent witnesses can agree in error, the probability of their future testimony being false is $\frac{1}{10,000}$ or $\frac{1}{(100)^2}$.

The reader will already perceive how great a reliance is due to the *future* concurring testimony of two independent witnesses of tolerably good character and understanding. It appears that, previously to the testimony, the chance of one such witness being in error is $\frac{1}{(100)^1}$; that of two concurring in the same error is $\frac{1}{(100)^2}$; and if the same reasoning be applied to three independent witnesses, it will be

found that the probability of their agreeing in error is $\frac{1}{(100)^3}$; or that the odds are 999,999 to 1 against the agreement.

Pursuing the same reasoning, the probability of the falsehood of a fact which six such independent witnesses attest is, previously to the testimony, $\frac{1}{(100)^6}$ or it is, in round numbers,

1,000,000,000,000 to 1 against the falsehood of their testimony.

The improbability of the miracle of a dead man being restored, is, on the principles stated by Hume, $\frac{1}{20(100)^5}$; or it is—

200,000,000,000 to 1 against its occurrence.

It follows, then, that the chances of accidental or other independent concurrence of only *six* such independent witnesses, is already *five times* as great as the improbability against

the miracle of a dead man's being restored to life, deduced from Hume's method of estimating its probability solely from experience.

This illustration shows the great accumulation of probability arising from the concurrence of independent witnesses: we must however combine this principle with another, before we can arrive at the real numerical value of the improbabilities referred to in the argument.

The calculation of the numerical values of these improbabilities I have given in Note (E.)

From this it results that, provided we assume that independent witnesses can be found of whose testimony it can be stated that it is more probable that it is true than that it is false, *we can always assign a number of witnesses which will, according to Hume's argument, prove the truth of a miracle.*

CHAPTER XI.

REFLECTIONS ON THE INQUIRY IN THE PRECEDING
CHAPTER.

THOSE who have too hastily lent the credit of their authority to support the prejudice, that the pursuit of mathematical investigations renders the mind unapt for the perception of the truths of religion, must now be compelled to admit that they have endeavoured to discredit a science, which alone can furnish an exact refutation of one of the most celebrated arguments against revelation. Those, on the other hand, who, without the knowledge which qualifies men to form opinions on such subjects, have obtruded their dogmatism on

the world, though they may fail to learn the lessons of caution and modesty, may yet be disposed to abstain from scattering their misdirected darts, lest they should injure one of the best allies of the faith which they profess. Whilst those, who in humble diffidence of their own powers, rely on the opinions of others, and are believers from feeling rather than from reason, may learn from experience what they might fail to ascertain by inquiry, “*that no TRUTH in any department of knowledge can ever be in contradiction to any other TRUTH;*”—and they may after many such instances perceive, that it is no narrow evidence which has convinced the most enlightened men, that unlimited discussion is the fatal enemy of error—the most certain supporter of truth.

In the course of this inquiry, the gradually decreasing value of human testimony, when transmitted from witness to witness, has been alluded to, and its bearing on the future

reception of revelation must have been foreseen by some, and may, when pointed out, be feared by others, of my readers. It may be apprehended, that after thousands of years, the long transmitted testimony of revealed truth, may not have sufficient force to convince the inquirers of that distant time. That such a cause is in constant action must be fully admitted, for every statement from man to his fellow man is liable to error from two sources. The witness may be deceived, or he may himself be a deceiver; and however extensive his knowledge, or however high his general character for veracity, whilst the possibility of a failure in either direction remains, repeated transmission through a series of such witnesses, will ultimately reduce to insignificance any statement in itself highly improbable. To suppose human beings incapable of being deceived and incapable of deception, is to assign to them attributes which we know they do not possess, and which we can scarcely assign to responsible and created beings.

Let us examine then what reply reason and science can make to such forebodings. If a transmitted revelation contain within its pages a prophecy of events, dark and unintelligible in itself, and therefore unfit to cause its own fulfilment ; and if from time to time facts occur, explaining instantly by no circuitous or lengthened process, but clearly and explicitly, the mystic words ; if the explanation of that, which till then was dark and mysterious even to the learned and reflecting, flashes with spontaneous conviction on the minds of multitudes, who now discover for the first time the events to have been clearly predicted ;—then a revelation, however faint from the lapse of time, revives with renewed energy, and claims its reception with a force almost equal to that which it demanded from those to whom it was originally delivered.

If, on the other hand, an inspired writer had given an account of a former state of our planet, different wholly from its present con-

dition, yet so distinct and minute, that if there were placed before us a map of the islands, continents, and rivers, with the plants and the animals of that ancient world, we should instantly recognise the coincidence with the prophet's description, and if it were impossible, from the state of knowledge when the revelation was delivered, that the writer could have been acquainted even with the relics of that former world he so well described, then it must be admitted, that we should have strong and irresistible evidence of his veracity.

Let us suppose an inspired writer to describe a former constitution of our globe, in which a vast continent occupied the position now filled by the Pacific Ocean ; that a great river with three outlets poured its waters towards the south ; that these streams and their banks were peopled with animals differing as much from all then known races, as the plesiosaurus and the pterodactyl do from those which now inhabit our globe, and that he had described, not with anatomical precision but in popular

language, the number of bones in the several parts of their frames, their habits, and food, as well as the plants which flourished on the banks of those rivers.

Thousands, or perhaps hundreds of thousands of years hence, we may conceive an island rising from the same ocean, and the geologists of that distant era tracing in its then elevated strata, by their fossil shells of mingled fresh water and marine origin, the estuaries of the streams from which the strata were deposited ; discovering by the depth of their branches and their magnitude, that the river must have been formed from the drainage of some great continent ; and finally, that aided by the comparative anatomists and botanists of that day, they should reconstruct from the fossil bones embedded in the strata, the very animals and plants described by the prophet, and ascertain even their habits and their food. If similar discoveries and reconstructions of animals previously unknown, have been made in our own

times, almost in the infancy of these sciences, what advances may we not expect with the progress of time ?

What has been stated by way of illustration as resulting from some branches of natural science, is equally applicable under different circumstances to many others. Nor does this view present any thing irreconcilable with the wisdom and benevolence of the Creator. In the early stages of the world, before man had acquired knowledge to read the book of nature ever open to his view, direct revelation might be as necessary for his belief in a Deity, as for his moral government ; and this might from time to time be repeated. When civilization and science had fixed their abode amongst mankind, and when observations and reason had enabled man to penetrate some little way into the mysteries of nature, his conviction of the existence of a first great cause would gradually acquire additional strength from the use of his own faculties,

and when accumulating proofs had firmly established this great step, the recurrence of revelation might be less necessary for his welfare.

The ancient revelation would however *necessarily* lose a portion of its weight from its continued transmission, and thus by slow but inevitable steps, tend in the lapse of ages to extinction. It is possible, however, that that very revelation may contain within its pages the verification of its own truth, and that the advancement of man in the knowledge of the structure of the works of his Creator, might furnish continually increasing proofs of its authenticity; and that thus by the due employment of our faculties, we might not merely redeem revelation from the ravages of time, but give to it a degree of force strengthening with every accession to our knowledge, and ultimately forcing our understandings to assent to it even with a conviction great as that which had compelled

the belief of those to whom it was originally delivered.

It is not for the finite faculties of man to pronounce what *has been* the course chosen for his happiness by an all-wise Creator, but it may be permitted to him to meet the difficulty which *necessarily* arises from the fallible and fading nature of human testimony by pointing out one *possible* course in which, by the exertion of the highest faculties with which we have been blessed, we may make a nearer approach to the knowledge of the will of our Creator.

CHAP. XII.

ON THE NATURE OF A SUPERINTENDING
PROVIDENCE.

SOME of the readers of the former edition of this work, whilst they have admitted the exalted view of the Creator, which arises from considering his will as the development of laws of unbounded generality, have expressed regret that those views appeared to them, in some measure, to imply that we are less *immediately* the objects of his protecting care, — that he seems thus less constantly and less directly, our watchful Guardian and Protector.

This difficulty ultimately resolves itself into that of the reconciling foreknowledge with freewill. Without, however, entering at present on that abstruse discussion, there are some reflections which may at least afford a partial reply to the objection stated above.

In reverting to the first origin of our knowledge of the motives and feelings of those around us, we must necessarily look into our own hearts. When we exercise that feeling which is called kindness or benevolence, we are conscious that we make some exertion, or some sacrifice, to add to the happiness of another person, without ourselves expecting to derive any advantage in return. When we observe other persons making similar exertions or sacrifices, and when we can discover no possibility of their deriving advantage from them, except that interior feeling of happiness which always arises from the exercise of such good offices, we conclude that they are actuated by the same feeling of kindness or benevolence.

In the first case we are conscious of the existence of that feeling within our own bosoms ; in the second we infer that it exists in others, from the similarity of human actions under the same apparent circumstances.

The *reasoning* which leads us to ascribe the attribute of benevolence to the Creator, is of precisely the same kind, although the infinity of this, as of his other attributes, can bear no comparison to the finite extent of those of other beings. Since however it is by such reasoning only that we attain the knowledge of them, so, if there arise a question about the comparative amount of any of those attributes when exerted in one way rather than in another, we must apply to such cases the same *reasoning*.

The inference from which the objection has arisen, is that the superintendence of Providence is remote, not immediate ; the answer that I shall endeavour to make to it is, that

the value of benevolence is not diminished by the distance of time at which its exertion arises.

In order to examine this question of immediate or remote superintendence, let us imagine a case occurring amongst our fellow-creatures, and let us endeavour to ascertain the conclusion we should form with regard to it.

Let us suppose the wealthy resident near a small village, returning from the neighbouring town, to have observed from a distance that the bridge across a rapid stream has been carried away by a flood, and that the blind postman who makes his daily journey along the causeway to the neighbouring town, unconscious of what has happened, is just approaching the torrent. Setting spurs to his horse, he dashes forward, and clearing the broken bridge, has just time to alight and catch the postman on the verge of destruction..

Such conduct is an example of kindness or benevolence, and would receive the praise it justly merits.

Let us now suppose another village,—another stream,—and another postman starting, like the former one, at an early hour, before the villagers are abroad. We will imagine too the wealthy resident near this other village to have been out on the preceding day amongst the distant mountains, from which the torrent which passes the village is fed; and that observing the quantity of rain which has fallen in those parts, he foresees that the resulting flood will in all probability destroy the bridge across that stream; and knowing from his experience that several hours must elapse before the rain which falls in the mountains produces its full effect on the stream in his neighbourhood, he sends off one of his attendants in time to reach the broken bridge just before the moment when the stream

would be crossed by the unsuspecting traveller, who is thus saved from death.

Undoubtedly this is benevolence. And although we may not infer, that the benevolence in the latter, was greater than in the former case, yet it cannot for a moment be maintained to be less. In fact, the first case was one of benevolence excited by feeling; in the second it was benevolence called forth by reflection, and aided and reduced to action by reasoning founded upon knowledge. The sportsman in the mountains who thus reasoned, would not have been less active had he been on the spot at the dangerous moment. But he who by his personal exertion preserved the blind man, although of an equally benevolent heart, might not have possessed the knowledge available for the safety of the postman, had he been at a distance from the spot on which his effort was successful.

Two inferences are connected with this imagined case.

1st, That the benevolence which organizes beforehand contrivances for the advantage or security of its objects, is at least as high as that which acts from the impulse of immediate feeling.

2d, That the benevolence which is guided by knowledge, even though, as a feeling, it may not be superior in intensity, is often of far more value to those who are its subjects.

Such are the decisions we should arrive at respecting human feelings and human knowledge; and applying the same principles instead of looking with any feelings of doubt or apprehension at the distance of time at which it may have pleased the Creator to have organized our protection from danger, we ought, when once convinced of his benevolence, to discover

in that very distance, proof of his higher knowledge and higher power, and with every addition to those attributes, to feel ourselves under still more potent and unintermitted watchfulness.

CHAP. XIII.

A PRIORI ARGUMENT IN FAVOUR OF THE OCCURRENCE OF MIRACLES.

IN the present chapter it is proposed to prove, that—

It is more probable that any law, at the knowledge of which we have arrived by observation, shall be subject to one of those violations which, according to Hume's definition, constitutes a miracle, than that it should not be so subjected.

To show this, we may be allowed again to revert to the Calculating Engine: and to assume that it is possible to set the

machine, so that it shall calculate *any algebraic law whatsoever* : and also possible so to arrange it, that at any periods, *however remote*, the first law shall be interrupted for one or more times, and be superseded by *any other law* ; after which the original law shall again be produced, and no other deviation shall ever take place.

Now, as all laws, which appear to us regular and uniform in their course, and to be subject to no exception, can be calculated by the engine : and as each of these laws may also be calculated by the same machine, subject to any assigned interruption, at distinct and definite periods ; each simple law may be interrupted at any point by the temporary action of a portion of any one of all the other simple laws : it follows, that *the class of laws subject to interruption is far more extensive than that of laws which are uninterrupted*. It is, in fact, infinitely more numerous. Therefore, the probability of any law with which we have become acquainted

by observation being part of a much more extensive law, and of its having, to use mathematical language, singular points or discontinuous functions contained within it, is very large.

Perhaps it may be objected, that the laws calculated by such an engine as I have referred to are not laws of nature; and that any deviation from laws produced by human mechanism does not come within Hume's definition of miracles. To this it may be answered, that a law of nature has been defined by Hume to rest upon experience, or repeated observation, just as the truth of testimony does. Now, the law produced by the engine may be arrived at by precisely the same means—namely, repeated observation.

It may, however, be desirable to explain further the nature of the evidence, on which the fact, that the engine possesses those powers, rests.

When the Calculating Engine has been set to compute the successive terms of any given law, which the observer is told will have an apparent exception (at, for example, the ten million and twenty-third term,) the observer is directed to note down the commencement of its computations; and, by comparing these results with his own independent calculations of the same law, he may verify the accuracy of the engine as far as he chooses. It may then be demonstrated to him, by the very structure of the machine, that if its motion were continued, it would, *necessarily*, at the end of a very long time, arrive at the ten-millionth term of the law assigned to it; and that, by an equal *necessity*, it would have passed through all the intermediate terms.* The inquirer is now desired to turn on the wheels with his own hand, until they are precisely in the same situation as they would have been had the engine itself gone on continuously, to the ten-millionth term. The machine is again put in motion,

* This can be done in a few minutes.

and the observer again finds that each successive term it calculates fulfils the original law. But, after passing twenty-two terms, he now observes *one* term which does not fulfil the original law, but which does coincide with the predicted exception.

The continued movement now again produces terms according with the first law, and the observer may continue to verify them as long as he wishes. It may then be demonstrated to him, by the very structure of the machine, that, if its motion were continued, it would be *impossible* that any other deviation from the apparent law could ever occur at any future time.

Such is the evidence to the observer ; and, if the superintendent of the engine were, at his request, to make it calculate a great variety of different laws, each interrupted by special and remote exceptions, he would have ample ground to believe in the assertion of its director, that he could so arrange the engine that any

law, however complicated, might be calculated to any assigned extent, and then there should arise one apparent exception ; after which the original law should continue uninterrupted for ever.

Let us now consider the miracle alluded to by Hume—the restoration of a dead man to life. According to the definition of that author, our belief that such a fact is contrary to the laws of nature, arises from our uniform experience against it. Our personal experience is small : we must therefore have recourse to testimony ; and from that we learn, that the dead are *never* restored to life ; and, consequently, we have the uniform experience of all mankind since the creation, against one assigned instance of a dead man being so restored. Let us now find the numerical amount of this evidence. Assuming the origin of the human race to have been about six thousand years ago, and taking thirty years as the duration of a generation, we have—

$$\frac{6000}{30} = 200 \text{ generations.}$$

And allowing that the average population of the earth has been a thousand millions, we find that there have been born and have died since the creation,

$$\begin{aligned} & 200 \times 1,000,000,000 \\ & = 200,000,000,000 \text{ individuals.} \end{aligned}$$

Such, then, according to Hume, are the odds against the truth of the miracle : that is to say, it is found from experience, that it is about two hundred thousand millions to one against a dead man having been restored to life.

Let us now compare this with a parallel case in the calculations of the engine ; let us suppose the number above stated to be a hundred million times as great, or that the truth of the miracles is opposed by a number of instances, expressed by twenty places of figures.

The engine may be set to count the natural numbers—1, 2, 3, 4, &c. ; and it shall continue to fulfil that law, not merely for the number of times just mentioned, for that number is quite insignificant among the vast periods it involves ; but the natural numbers shall follow in continual succession, until they have reached an amount which requires for its expression above a hundred million places of figures. If every letter in the volume now before the reader's eyes were changed into a figure, and if all the figures contained in a thousand such volumes were arranged in order, the whole together would yet fall far short of the vast induction the observer would then have had in favour of the truth of the law of natural numbers. The widest range of all the cycles of astronomy and geology combined, sink into insignificance before such a period. Yet, shall the engine, true to the prediction of its director, after the lapse of myriads of ages, fulfil its task, and give that one, the *first* and *only* exception to that time-sanctioned law. What would have

been the chances against the appearance of the excepted case, immediately prior to its occurrence? It would have had, according to Hume, the evidence of all experience against it, with a force myriads of times more strong than that against any miracle.

Now, let the reader, who has fully entered into the nature of the argument, ask himself this question:—Does he believe that such an engine has really been contrived, and what reasonable grounds has he for that belief?

The testimony of any single witness is small against such odds; besides, the witness may deceive himself. Whether he speaks truly, will be estimated by his moral character—whether he deceives himself, will be estimated by his intellectual character. The probability that such an engine has been contrived, will, however, receive great addition, when it is remarked, that mathematical—and, especially, geometrical evidence is, of all others, that in

which the fewest mistakes arise, and in which they are most readily discovered ; and when it is added, that the fact of the invention of such an engine rests on precisely the same species of evidence as the propositions of Euclid, and may be deduced from the drawings with all the force of demonstration. Whether such an engine could be actually made in the present state of mechanical art, is a question of quite a different order : it must rest upon the opinions of those who have had extensive experience in that art. The author has not the slightest hesitation in stating his opinion to be, that it is fully within those limits.

This, however, is a question foreign to the nature of the argument, which might have been stated in a more abstract manner, without any reference to such an engine. As, however, the argument really arose from that machine, and as visible forms make a much deeper impression on the mind than any abstract reasonings, it has been stated in conjunction with that subject.

CHAPTER XIV.

THOUGHTS ON THE NATURE OF FUTURE
PUNISHMENTS.

Who has not felt the painful memory of departed folly? who has not at times found crowding on his recollection, thoughts, feelings, scenes, by all perhaps but himself forgotten, which force themselves involuntarily on his attention? Who has not reproached himself with the bitterest regret at the follies he has thought, or said, or acted? Time brings no alleviation to these periods of morbid memory: the weaknesses of our youthful days, as well as those of later life, come equally

unbidden and unarranged, to mock our attention and claim their condemnation from our severer judgment.

It is remarkable that those whom the world least accuses, accuse themselves the most ; and that a foolish speech, which at the time of its utterance was unobserved as such by all who heard it, shall yet remain fixed in the memory of him who pronounced it, with a tenacity which he vainly seeks to communicate to more agreeable subjects of reflection. It is also remarkable that whilst our own foibles, or our imagined exposure of them to others, furnish the most frequent subject of almost nightly regret, yet we rarely call to recollection our acts of consideration for the feelings of others, or those of kindness and benevolence. These are not the familiar friends of our memory, ready at all times to enter the domicile of mind its welcome but unbidden guests. When they appear, they are usually summoned at the command of reason, to meet some

expected ingratitude, or when the mind retires within its council chamber to nerve itself for the endurance or the resistance of injustice.

If such be the pain, the penalty of thoughtless folly, who shall describe the punishment of real guilt? Make but the offender better, and he is already severely punished. Memory, that treacherous friend but faithful monitor, recalls the existence of the past, to a mind now imbued with finer feelings, with sterner notions of justice than when it enacted the deeds thus punished by their recollection.

If additional knowledge be given to us, the consequences of many of our actions appear in a very altered light. We become acquainted with many evils they have produced, which, although quite unintentional on our part, are yet subjects of painful regret. But this unavailing regret is mixed with another feeling far more distressing. We reproach ourselves with not having sufficiently employed the faculties we

possessed in acquiring that knowledge, which, if we had attained it, would have prevented us from committing acts we now discover to have been injurious to those we best loved.

On the other hand, the good which such increased knowledge enables us to discover that we have *unintentionally* done, fails to produce the satisfaction always arising from a virtuous motive ; and it is accompanied by the regret that, by a sufficient cultivation of our faculties, we might have enjoyed a still higher gratification, by a more efficient service to our fellow-creatures.

Thus, on whichever side we look at the question, knowledge *alone* is advantageous to virtue ; and if additional knowledge *alone* were given in a future life, it would cause the best of us to regret the errors of the present.

Let us now consider the consequences of a higher tone of moral feeling—of a perception

of excellencies of character in others, hitherto unappreciated.

Without the torment arising from additional knowledge, we may, in such circumstances, perceive, that the pain we have inflicted for imagined offences was quite beyond their real deserts; and may feel that the justice we have done to others, has been quite disproportioned to the sacrifices they have made to serve us.

If, without any addition to our intellectual faculties, increased perfection were given to our bodily senses, the same result would ensue. Wollaston has shown, that there are sounds of such a nature, that they can be heard by some individuals, but are inaudible to others,—a circumstance which may arise either from the incapacity of the parts of the ear to vibrate in the same time as those producing the sound, or from the force of the sounding body being insufficient to communicate motion through the

air to those portions of the ear whose movement is required to produce the sensation of hearing.

If we imagine the soul in an after stage of our existence, to be connected with a bodily organ of hearing so sensitive, as to vibrate with motions of the air, even of infinitesimal force, and if it be still within the precincts of its ancient abode, all the accumulated words pronounced from the creation of mankind, will fall at once upon that ear. Imagine, in addition, a power of directing the attention of that organ entirely to any one class of those vibrations: then will the apparent confusion vanish at once; and the punished offender may hear still vibrating on his ear the very words uttered, perhaps, thousands of centuries before, which at once caused and registered his own condemnation.

It seems, then, that either with improved faculties or with increased knowledge, we could scarcely look back with any satisfaction on our

past lives ;—that, to the major part of our race, oblivion would be the greatest boon. But if, in a future state, we could turn from the contemplation of our own imperfections, and with increased powers apply our minds to the discovery of nature's laws, and to the invention of new methods by which our faculties might be aided in that research, pleasure the most unalloyed would await us at every stage of our progress. Unclogged by the dull corporeal load of matter which tyrannizes even over our most intellectual moments, and chains the ardent spirit to its unkindred clay, we should advance in the pursuit, stimulated instead of wearied by our past exertions, and encountering each new difficulty in the inquiry, with the accumulated power derived from the experience of the past, and the irresistible energy resulting from the confidence of ultimate success.

Whether, then, we regard our future prospects as connected with a far higher acuteness of our present senses—or, as purified by more

exalted moral feelings—or, as guided by intellectual power surpassing all we contemplate upon earth, we equally arrive at the conclusion, that the mere employment of such enlarged faculties, in surveying our past existence, will be an ample punishment for all our errors ; whilst, on the other hand, if that Being who assigned to us those faculties, should turn their application from the survey of the past, to the inquiry into the present and to the search into the future, the most enduring happiness would arise from the most inexhaustible source.

CHAP. XV.

REFLECTIONS ON FREE WILL.

THE great question of the incompatibility of one of the attributes of the Creator—that of fore-knowledge, with the existence of the free exercise of their will in the beings he has created,—has long baffled human comprehension ; nor is it the object of this chapter to enter upon that difficult question.

As, however, some of the properties of the Calculating Engine seem, although but very remotely, to bear on a similar question, with respect to finite beings, it may, perhaps, not be entirely useless to state them.

It has already been observed, that it is possible so to adjust the engine, that it shall change the law it is calculating into another law, at any distant period which may be assigned.

Now, by a similar adjustment, this change may be made to take place at a time not foreseen by the person employing the engine. For example : when calculating a table of squares, it may be made to change into a table of cubes, the first time the square number ends in the figures—

269696 ;

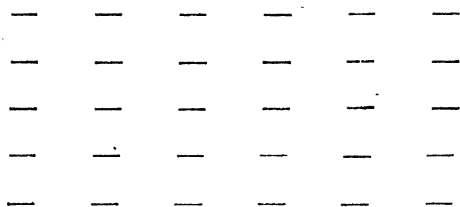

an event which only occurs at the 99736th calculation ; and whether that fact is known to the person who adjusts the machine or not, is immaterial to the result.

But the very condition on which the change depends, may be impossible. Thus, the change of the law from that of squares to that of cubes may be made to take place the first time

the square number ends in 7. But it is known, that no square number can end in a 7 ; consequently the event, on the happening of which the change is determined, can itself never take place. Yet, the engine retains impressed on it a law, which would be called into action if the event on which it depends could occur in the course of the law it is calculating.

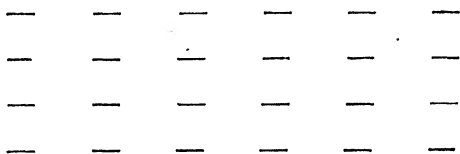

Nay, further, if the observer of the engine is informed, that at certain times he can move the last figure the engine has calculated, and change it into any other, in consequence of which it becomes possible that some future term may end in 7 ; then, after he has so changed the last figure, whenever that terminal figure arrives, all future numbers calculated by the machine will follow the law of the cubes.

—	—	—	—	—	—
—	—	—	—	—	—
—	—	—	—	—	—

These contingent changes may be limited to single exceptions, and the arrival of such an exception may be made contingent on a change which is only possible at certain rare periods. For example: the engine may be set to calculate square numbers, and after a certain number of calculations—ten million and fifty-three, for instance, it shall be possible to add unity to a wheel in another part of the engine, which in every other case is immovable. This fact being communicated to the observer, he may either make that addition or refrain from it: if he refrain, the law of the squares will continue for ever; if he make the addition, one single cube will be substituted for that square number, which ought to occur ten million and five terms beyond the point at which he made

the addition ; and after that no future addition will ever become possible, and no deviation from the law of the squares ever can occur.

CONCLUSION.

READER, I have now fulfilled the task I undertook. Labouring under that imputed mental incapacity which the science I cultivate has been stated to produce, I have brought from the recesses of that science the reasonings and illustrations by which I have endeavoured faintly to embody the human conception of the Almighty mind. It is for you to determine whether the trains of thought I have excited have lowered or exalted your previous notions of the power and the knowledge of the Creator.

That prejudice which I have endeavoured to expose is not a merely speculative opinion, it is a practical evil; and those whose writings have been supposed to give support to it, will, I am sure, feel grieved when they learn that it is used by the ignorant and the designing, for the injury of the virtuous and the instructed; that it is employed as a firebrand, to disturb the relations of social life. They will also, if the arguments I have used have the same effect on their minds which they have had upon my own, lament still more deeply that they should have contributed, in any degree, to throw discredit on that species of knowledge which is now found to supply some of the strongest arguments in favour of religion. I will, however, hope that the opinions I have combated are not shared or even countenanced by the higher authorities of our Protestant Church; and I cannot better conclude this Fragment, than by recalling to the reader the words of one, whose power of reasoning, and whose love of truth, add

dignity to the high station he so deservedly fills :—

“ Lastly, As we must not dare to withhold
“ or disguise revealed *religious* truth, so, we
“ must dread the progress of no *other* truth.
“ We must not imitate the bigoted Romanists
“ who imprisoned Galileo ; and step forward
“ Bible in hand (like the profane Israelites carrying the Ark of God into the field of battle)
“ to check the inquiries of the Geologist, the
“ Astronomer, or the Political-economist, from
“ an apprehension, that the cause of religion
“ can be endangered by them.* Any theory
“ on whatever subject, that is really sound, can
“ never be inimical to a religion founded on
“ truth ; and any that is unsound may be refuted by arguments drawn from observation
“ and experiment, without calling in the aid of
“ revelation. If we give way to a dread of
“ danger from the inculcation of any scriptural

* See First Lecture on Political Economy.

“ doctrine, or from the progress of physical or
“ moral science, we manifest a want of faith in
“ God’s power, or in his will, to maintain his
“ own cause. That we shall indeed best fur-
“ ther his cause by fearless perseverance in an
“ open and straight course, I am firmly per-
“ suaded; but it is not only when we *perceive*
“ the mischiefs of falsehood and disguise, and
“ the beneficial tendency of fairness and can-
“ dour, that we are to be followers of truth:
“ the trial of our faith is, when we *cannot* per-
“ ceive this: and the part of a lover of truth
“ is to follow her at all seeming hazards, after
“ the example of Him who ‘came into the
“ world that He might bear witness to the
“ Truth.’”*

NOTE A. PAGE 32.

ON THE GREAT LAW WHICH REGULATES MATTER.

EVER since the period when Newton established the great law of gravity, philosophers have occasionally speculated on the existence of some more comprehensive law, of which gravity itself is a consequence. Although some have considered it vain to search for a more general law, the great philosopher himself left encouragement to future inquirers; and the time, perhaps, has even now arrived, when such a discovery may be near its maturity. It would occupy too much space to introduce many illustrations of this opinion; there is, however, one which deserves attention, because it is not merely a happy conjecture, but the hypothesis on which it rests has been carried out by its author, through the aid of profound mathematical reasoning, to many of its remote consequences.

M. Mosotti* has shown, that by supposing matter to consist of two sorts of particles, each of which repels similar particles, directly as the mass, and inversely as the squares of their distances, whilst each attracts those of the other kind, also according to the same law,—then the resulting attractions explain all the phenomena of electricity, while there remains a residual force, acting at all sensible distances, according to the law of gravity.

Many of the discoveries of the present day point towards some more general law; and many philosophers of the present time anticipate its near approach. Under these circumstances, it may be interesting as well as useful briefly to state the principles which such a law *must* comprehend; and to indicate, however imperfectly, the path to be pursued in the research.

If matter be supposed to consist of two sorts of particles, or rather, perhaps, of two sorts of centres of force, of different orders of density; and if the particles of each order repel their own particles, according to a given law, but attract particles of the other kind, according to another law,—then, if we conceive only one particle of the denser kind to exist, and an infinite

* Professor of Physics at the University of the Ionian Islands.—The paper of M. Mosotti has been translated, and published by Mr. R. Taylor, in the third number of the Scientific Memoirs; a work which it is proposed shall contain translations of all the most important *original* papers printed in foreign countries.

number of the other kind, that single particle will become the centre of a system, surrounded by all the others, which will form around it an atmosphere denser near the central body.

If we conceive a stream of particles, similar to those forming the atmosphere, to impinge upon it, so as just to overcome its resistance, they will, whilst continually producing undulations throughout its whole extent, gradually increase its magnitude, until it attains such a size, that the repulsion of the particles at the outer surface of this enlarged atmosphere is just balanced by the attraction of the central particle. If the stream continue after this point is reached, the whole outer layer will be pressed a little beyond the limit of attraction, and will fly off at right angles to the surface, which might then be said to radiate.

If the whole of the space in which such a central particle with its atmosphere is placed, is itself full of atmospheric particles, then their density will increase in approaching the central body; and if a stream of such particles were directed towards the centre, they might produce throughout the atmosphere vibrations, which would be transmitted from it in all directions.

If two such central particles, with their atmospheres, exist at a distance from each other, they will be drawn together by a force depending on the *difference* between

the mutual repulsion of their atmospheres and central bodies respectively for each other, and the attraction of each central particle for its neighbour's atmosphere : and in order to coincide with the existing law of nature, this force must be directly as the mass, and inversely as the square, of the distance. The other conditions which such a law must satisfy, are—

1. That the juxtaposition of such atoms must, in some circumstances, form a solid body:—

2. In other circumstances, a fluid.

3. That again, in still other circumstances, its particles shall repel each other, or the body become gaseous.

4. In the first state the body must possess cohesion, tenacity, malleability, elasticity ; the measure and extent of each of which must result generally from the original law, and in each particular case from the constants belonging to the substance itself.

5. In the second state, it must possess capillarity, susceptibility of being compressed without becoming solid, as also elasticity.

But besides these, the *central* atoms must admit of a more intimate approach, so that their atmospheres may

unite and form one atmosphere. This might constitute chemical union. Binary compounds might then (supposing the distance between the two central particles to be very small, compared with the diameters of the atmospheres) have atmospheres not quite spherical, and attracting differently in different directions; thus possessing polarity. Combinations of three or more atoms, as the central body of one atmosphere, might give great varieties of attractive forces. Each different combination would give a different atmosphere; and the equation of its surface might, perhaps, become the mathematical expression of the substance it constituted. Thus, all the phenomena produced by bodies, acting chemically on each other, might be deduced from the comparison of the *characteristic* surfaces of the atmospheres of their atoms. Another result, also, might ensue. Two or more central atoms uniting, might either not be able to retain the same amount of atmosphere, or they might possibly be able to retain a larger quantity. If the particles of such atmospheres constituted heat, it would in the former case be given out, and in the latter absorbed by chemical union.

Hence the whole of chemistry, and with it crystallography, would become a branch of mathematical analysis, which, like astronomy, taking its constants from observation, would enable us to predict the character of any new compound, and possibly indicate the source from which its formation might be anticipated.

For the sake of simplicity, two species of particles only have been mentioned above; but it seems more probable, that matter consists of at least three kinds.

Suppose each of the three kinds to repel its own particles; and the central atom, whilst it repels similar particles, to attract those of the two other kinds; and moreover, that the latter are either repulsive, or indifferent to each other. We might then conceive matter to be made up of particles, each having a central point, with an atmosphere surrounding it, and this atmosphere again inclosed within another and larger one.

Under such circumstances, the outer atmosphere might give rise to heat and light, to solidity and fluidity, and the gaseous condition; to capillarity, to elasticity, tenacity, and malleability. The more intimate union of the central atoms, by which two or more become enclosed in one common atmosphere of the second kind, might represent chemical combinations, and perhaps that atmosphere itself be electricity. Possibly, also, this intermediate atmosphere, acted on by the pressure of the external one, and by the attraction of the central atom, might take the liquid form. These binary or multiple-combinations of the original atoms, and their smaller atmospheres, would still be enclosed in an atmosphere of the outer kind, which might be nearly spherical. The joint action of the three might, at sensible distances, produce gravity.

The reader should, however, bear in mind, that these hints are thrown out only as objects of reflection and inquiry; and that nothing but a profound mathematical investigation can establish them, or even give to them that temporary value which arises from any hypothesis, representing a large collection of facts.

NOTE B. PAGE 33.

ON THE CALCULATING ENGINE.

THE nature of the arguments advanced in this volume having obliged me to refer, more frequently than I should have chosen, to the Calculating Engine, it becomes necessary to give the reader some brief account of its progress and present state.

About the year 1821, I undertook to superintend, for the Government, the construction of an engine for calculating and printing mathematical and astronomical tables. Early in the year 1833, a small portion of the machine was put together, and was found to perform its work with all the precision which had been anticipated. At that period circumstances, which I could not control, caused what I then considered a temporary suspension of its progress; and the Government, on whose

decision the continuance or discontinuance of the work depended, have not yet communicated to me their wishes on the question. The first illustration (p. 33 to 43) I have employed is derived from the calculations made by this engine.

About October, 1834, I commenced the design of another, and far more powerful engine. Many of the contrivances necessary for its performance have since been discussed and drawn according to various principles; and all of them have been invented in more than one form. I consider them, even in their present state, as susceptible of practical execution; but time, thought, and expense, will probably improve them. As the remaining illustrations are all drawn from the powers of this new engine, it may be right to state, that it will calculate the numerical value of any algebraical function—that, at any period previously fixed upon, or contingent on certain events, it will cease to tabulate that algebraic function, and commence the calculation of a different one, and that these changes may be repeated to any extent.

The former engine could employ about 120 figures in its calculations; the present machine is intended to compute with about 4,000.

Here I should willingly have left the subject; but the public having erroneously imagined, that the sums

of money paid to the workmen for the construction of the engine, were the remuneration of my own services, for inventing and directing its progress; and a Committee of the House of Commons having incidentally led the public to believe that a sum of money was voted to me for that purpose,—I think it right to give to that report the most direct and unequivocal contradiction.

EXTRACT FROM THE THEORY OF PROBABILITIES OF
LAPLACE.

“ Nous devons donc envisager l'état présent de l'univers, comme l'effet de son état antérieur, et comme la cause de celui qui va suivre.

“ Une intelligence qui pour un instant donnée, connaîtrait toutes les forces dont la nature est animée, et la situation respective des êtres qui la composent, si d'ailleurs elle était assez vaste pour soumettre ces données à l'analyse, embrasserait, dans la même formule, les mouvemens des plus grands corps de l'univers et ceux du plus léger atome : rien ne serait incertain pour elle, et l'avenir, comme le passé, serait présent à ses yeux. L'esprit humain offre, dans la perfection qu'il a su donner à l'astronomie, une faible esquisse de cette intelli-

gence. Ses découvertes en mécanique et en géométrie, jointes à celle de la pesanteur universelle, l'ont mis à portée de comprendre dans les mêmes expressions analytiques, les états passés et futurs du système du monde.

“ En appliquant le même méthode à quelques autres objets de ses connaissances, il est parvenu à ramener à des lois générales, les phénomènes observés, et à prévoir ceux que des circonstances données doivent faire éclore. Tous ses efforts dans la recherche de la vérité, tendent à le rapprocher sans cesse à l'intelligence que nous venons de concevoir, mais dont il restera toujours infiniment éloigné. Cette tendance propre à l'espèce humaine, est ce qui la rend supérieure aux animaux ; et ses progrès en ce genre, distinguent les nations et les siècles, étendent leur véritable gloire.” — *Laplace, Théorie Analytique des Probabilités.*

NOTE D. PAGE 92.

NOTE TO CHAP. VIII. ON MIRACLES.

THE view taken of miracles in Chapter VIII. is the same as that contained in the work of Butler, on the Analogy of Religion to the Constitution and Course of Nature. Inquiries connected with the Calculating Engine, impressed it very forcibly on my own mind, and I have drawn the illustrations chiefly from that subject. I cannot, however, forbear referring the reader to the opinion of Sir J. Herschel, expressed at the beginning of his letter to Mr. Lyell, (see Note I. p. 225,) because it confirms me in the belief, that the more profoundly we inquire into the mechanism of nature, the more certainly we arrive at that conclusion.

NOTE E. PAGE 131.

NOTE TO CHAPTER X. ON HUME'S ARGUMENT
AGAINST MIRACLES.

THE reader will observe, that throughout the chapter to which this note refers, as well as in the note itself, the argument of Hume is taken strictly according to his own interpretation of the terms he uses, and the calculations are founded on them; so that it is from the very argument itself, when fairly pursued to its full extent, that the refutation results.

Both our belief in the truth of human testimony, and our belief in the permanence of the laws of nature, are, according to Hume, founded on experience; we may, therefore, in the complete ignorance in which he assumes we are, with respect to the causes of either, treat the question as one of the probability of an event deduced solely from observations of the past.

The argument of Hume asserts, that one improbability, namely, that of the falsehood of the testimony in favour of a miracle, must always be *greater* than another improbability, namely, that of the occurrence of the miracle itself; and also, that, from the very nature of human experience, this preponderance can *never* take place.

Now the ONLY POSSIBLE mode of disproving the assertion, that one thing cannot, under any circumstances, be greater than another, is to measure, under all circumstances, the numerical value of the two things so compared, and the truth or falsehood of the assertion will then appear. The doctrine of chances, which has been much improved since the time of Hume, now enables us to apply precise measures to this argument; and it is the object of this Note to state the outlines of the calculation, and the results to which it leads. Previously to this, however, it may not be amiss to offer a few remarks on the principles about to be employed.

In the great work of Laplace, "Théorie Analytique des Probabilités," those principles are established, and they are not merely undisputed, but are admitted by other writers of the highest authority on this subject. They form a part of the received knowledge of the present day, and, as such, they are employed in the present work, in which I propose to use, not to

discuss them. I state this, because it has occasionally been asserted by persons unacquainted with the doctrine of chances, that the argument respecting the probability or improbability of miracles does not admit of the application of numbers. The received foundations of science are not to be put aside by such opinions, however highly skilled their authors may be in other branches of knowledge, and however powerful the intellect by which they may have attained those acquirements. The conclusions arrived at by the application of pure analysis must ever rest on the truth of the principles assumed at the commencement of the inquiry; and although a knowledge of mathematics may not appear necessary for forming a right judgment of the accuracy of those principles, yet it is observed, that a clear apprehension of them is not often found in the minds of those who are unacquainted with that science. When, however, the grounds on which the principles employed in the doctrine of chances are called in question by competent authority, it will be time enough to examine the question; and none will more eagerly enter upon that examination than those best versed in it, for none are so well aware of the extreme difficulty and delicacy of the subject.

As confusion sometimes arises from the difference in the meaning of the words *probable* and *improbable* in popular language and in mathematical inquiries,

it may be convenient to point it out; and to state, that in this Note it is used in the mathematical sense, unless the reader's attention is directly called to a question relating to its popular sense.

In common language, an event is said to be *probable* when it is more likely to happen than to fail: it is said to be *improbable* when it is more likely to fail than to happen.

Now, an event whose probability is, in mathematical language $\frac{1}{p}$, will be called probable or improbable, in ordinary language, according as p is less or greater than 2.

If, in mathematical language, $\frac{1}{p}$ expresses the *probability* of an event happening, $1 - \frac{1}{p}$ expresses the probability of its failing, or the *improbability* of its happening.

It has been stated in the text, that two views may be taken of those extraordinary deviations from the usual course of nature, called miracles. According to the first of these, we have to calculate the probability that a *white* ball has been drawn from an urn (containing only white and black balls, out of which m balls have been drawn all black), as deduced from

the testimony of witnesses whose probability of speaking truth is known:—or, of the analogous case; it having been observed that m persons have died without any restoration to life, what is the probability that such a resurrection has happened, it having been asserted by n independent witnesses, the probability of each of whose speaking false is $\frac{1}{p}$?

The probability of the death without resurrection of the $(m+1)^{\text{th}}$ is $\frac{m+1}{m+2}$, and the improbability of such an occurrence, independently of testimony, is $\frac{1}{m+2}$; which is therefore the probability of a contrary occurrence, or that of a person being raised from the dead.

Now only two hypotheses can be formed, collusion being, by hypothesis, out of the question: either the event did happen, and the witnesses agree in speaking the truth, the probability of their concurrence being $\left(1 - \frac{1}{p}\right)^n$, and of that of the hypothesis being $\frac{1}{m+2}$; or the event did not happen, and the witnesses agree in a falsehood, the probability of their concurrence being $\left(\frac{1}{p}\right)^n$, and that of the hypothesis $\frac{m+1}{m+2}$.

The probability of the witnesses speaking truth, and the event occurring, is therefore,

$$\frac{\left(1 - \frac{1}{p}\right)^n \frac{1}{m+2}}{\left(1 - \frac{1}{p}\right)^n \frac{1}{m+2} + \left(\frac{1}{p}\right)^n \frac{m+1}{m+2}} = \frac{(p-1)^n}{(p-1)^n + m+1}; \quad (A.)$$

and the probability of their falsehood is,

$$\frac{\left(\frac{1}{p}\right)^n \frac{m+1}{m+2}}{\left(1 - \frac{1}{p}\right)^n \frac{1}{m+2} + \left(\frac{1}{p}\right)^n \frac{m+1}{m+2}} = \frac{m+1}{(p-1)^n + m+1}. \quad (B.)$$

If we interpret Hume's assertion, "that the falsehood of the witnesses must be more improbable than the occurrence of the miracle," according to the mathematical meaning of the word improbable, then we must have,

$$\frac{m+1}{(p-1)^n + m+1} < \frac{1}{m+2};$$

or,

$$(m+1) \cdot (m+2) < (p-1)^n + m+1;$$

hence,

$$(p-1)^n > (m+1) \cdot (m+2) - (m+1) > (m+1)^2,$$

from which we find,

$$n > \frac{2 \log. (m+1)}{\log. (p-1)}.$$

If p is any number greater than two, this equation can always be satisfied.

It follows, therefore, that however large m may be, or however great the quantity of experience against the occurrence of a miracle, (provided only that there

are persons whose statements are more frequently correct than incorrect, and who give their testimony in favour of it without collusion,) a certain number n can ALWAYS be found; so that *it shall be a greater improbability that their unanimous statement shall be a falsehood, than that the miracle shall have occurred.*

Let us now suppose each witness to state one falsehood for every ten truths, or $p = 11$, and $m = 1000,000,000,000$;

$$\text{then, } n > \frac{2 \log.(10^{12} + 1)}{\log. 10} > 24.$$

or twenty-five such witnesses are sufficient.

If the witnesses only state one falsehood for every hundred truths, then thirteen such witnesses are sufficient.

Another view of the question might be taken; and it might be asserted that, in order to believe in the miracle, the probability of its truth must be greater than the probability of its falsehood; in this case the expression (A) must be greater than (B); or,

$$\frac{(p-1)^n}{(p-1)^n + m + 1} > \frac{m + 1}{(p-1)^n + m + 1};$$

$$\text{hence, } (p-1)^n > m + 1,$$

$$\text{and } n > \frac{\log.(m + 1)}{\log.(p - 1)}.$$

In this case also, under the same circumstances, the condition can always be fulfilled of finding a sufficient

number of witnesses to render the miracle probable, or even to give to it any required degree of probability.

If $p = 11$, and $m = 1000,000,000,000$, as before, then

$$n > \frac{\log. (10^{12} + 1)}{\log. 10} > 12.$$

According to the second view stated in the text, a miracle may be assimilated to the drawing of a given number i out of an urn, containing all numbers from one to m .

In this case the probability of the occurrence of the event is $\frac{1}{m}$, and the probability of the concurrence of n witnesses in falsehood is $\left(\frac{1}{p}\right)^n$.

Hence the probability that the particular number i was drawn, as deduced from the testimony of n witnesses, each of whose probability of falsehood is $\frac{1}{p}$, is expressed by,

$$\begin{aligned} & \frac{\left(1 - \frac{1}{p}\right)^n \frac{1}{m}}{\left(1 - \frac{1}{p}\right)^n \frac{1}{m} + \left(\frac{1}{p}\right)^n \left(1 - \frac{1}{m}\right) \left(\frac{1}{m-1}\right)^n} = \\ & \frac{(p-1)^n}{(p-1)^n + (m-1) \left(\frac{1}{m-1}\right)^n} = \\ & \frac{1}{1 + (m-1) \left(\frac{1}{m-1 \cdot p-1}\right)^n} \quad (C.) \end{aligned}$$

and the probability of the number i not having been drawn, or of their falsehood, is

$$\frac{\left(\frac{1}{p}\right)^n \left(1 - \frac{1}{m}\right) \left(\frac{1}{m-1}\right)^n}{\left(1 - \frac{1}{p}\right)^n \frac{1}{m} + \left(\frac{1}{p}\right)^n \left(1 - \frac{1}{m}\right) \left(\frac{1}{m-1}\right)^n} =$$

$$\frac{(m-1) \left(\frac{1}{m-1}\right)^n}{(p-1)^n + (m-1) \left(\frac{1}{m-1}\right)^n} =$$

$$\frac{m-1}{(p-1 \cdot m-1)^n + (m-1)} \quad (D.)$$

Hence the improbability of the testimony must, according to Hume, be greater than that of the occurrence of the event; or,

$$\frac{m-1}{(p-1 \cdot m-1)^n + m-1} < \frac{1}{m}.$$

Hence, $m \cdot \overline{m-1} < (\overline{p-1} \cdot \overline{m-1})^n + m-1$,
and, $(\overline{p-1} \cdot \overline{m-1})^n > m \cdot \overline{m-1} - m-1 > (m-1)^2$,

$$\text{or, } n > \frac{2 \log. (m-1)}{\log. (p-1) + \log. (m-1)}.$$

If $p = 11$, and $m = 1000,000,000,000$, as above,

$$n > \frac{2 \times 12}{1 + 12} > \frac{24}{13} > 2.$$

If it is only required that the probability of the occurrence of the miracle shall be greater than its

improbability, then we must make (C) greater than (D); or,

$$\frac{1}{1 + (m-1) \left(\frac{1}{m-1 \cdot p-1} \right)^n} > \frac{m-1}{(p-1 \cdot m-1)^n + m-1};$$

from which,

$$\frac{(m-1 \cdot p-1)^n}{(p-1 \cdot m-1)^n + m-1} > \frac{m-1}{(p-1 \cdot m-1)^n + m-1},$$

$$\text{or, } (m-1 \cdot p-1)^n > m-1.$$

$$\text{Hence, } n > \frac{\log. m-1}{\log. m-1 + \log. p-1}.$$

If $p = 11$, and $m = 1000,000,000,000$,

$$n > \frac{12}{12+1} > \frac{12}{13}.$$

Hence in this view, also, a sufficient number of witnesses of given veracity may *always* be found to render the improbability of their concurrent independent testimony being false, greater than the improbability of the occurrence of the miracle.

There is, however, one other view, which it seems probable would have been that taken by Hume himself, had he applied numbers to his own argument. Considering the probability of the coincidence in falsehood of n persons each having the probability $\frac{p-1}{p}$

in favour of his truth, which is $\frac{1}{p^n}$, that probability ought to be less than that of the occurrence of the miracle; or,

$$\frac{1}{p^n} < \frac{1}{m+2};$$

$$\text{hence, } p^n > m+2,$$

$$\text{or, } n > \frac{\log. (m+2)}{\log. p}.$$

According to this view also, if $m=1000,000,000,000$, and $p=11 > \frac{12}{1.04} > 12$.

This view of the question refers to the probability of the concurrence of the witnesses *before* they have given their testimony. The other four cases relate to the probability of the miracle having happened, as deduced from the fact of the testimony having been given. The last seems to have been that which Hume would have himself arrived at; the others represent the true methods of estimating the probabilities of the various cases: and the important conclusion follows, that, whichever be the interpretation given to the argument of Hume, if independent witnesses can be found, who speak truth more frequently than falsehood, *it is ALWAYS possible to assign a number of independent witnesses, the improbability of the falsehood of whose concurring testimony shall be greater than that of the improbability of the miracle itself.*

It is to be observed, that the whole of this argument applies to *independent* witnesses. The possibility of the collusion, and the degree of credit to be assigned to witnesses under any given circumstances, depend on facts which have not yet been sufficiently collected to become the subject of mathematical inquiry. Some of those considerations which bear on this part of the subject, the reader will find treated of in the work of Dr. Conyers Middleton, entitled "A Free Inquiry into the Miraculous Powers which are supposed to have subsisted in the Christian Church, from the earliest Ages through several successive Centuries." London, 1749.

NOTE F.

ON THE CONSEQUENCES OF CENTRAL HEAT.

THE increase of temperature observed as we descend below the earth's surface, as well as other phenomena, have led to a very general opinion, that great heat exists in the interior of the earth, and that the body of our planet, having been at one time intensely heated, has cooled down to its present temperature. With the view of pointing out courses of inquiry, by which these opinions may ultimately be tested by observation, it may be expedient to take a cursory view of some of the consequences of such an hypothesis.

And first, let us imagine the exterior of our globe to have once been in a state of intense heat. No fluid such as water could then have existed on the surface : it would instantly have been converted into vapour ; and

notwithstanding the increased weight of atmosphere thus produced and pressing on the surface of the globe, sufficient heat would reduce all fluids to the gaseous state. Let us, however, inquire as to the possible extent of such an atmosphere.

In the first place, it could not extend beyond that point at which the moon's attraction is equal to that of the earth. In the next place, much more contracted limits would be prescribed by the effect of centrifugal force, and of the cooling of the vapour by expansion, and by its distance from the source of radiant heat, which had caused its evaporation.

It would be interesting to inquire, what would be the nature of the surface of the atmosphere under such circumstances. At the distance at which the centrifugal force is equal to that of gravity, it might happen that the temperature was scarcely sufficient to maintain the water in a gaseous state. Should this have been the case, a belt of perpetual clouds might have been formed, resembling those of Jupiter. If, at this limit, a still lower degree of temperature prevailed, instead of a belt of clouds, a ring of ice might be formed.

This ring of ice, being exposed to different effects of radiation from variations in the radiating power of various parts of the earth's surface, might, by the superior heat at some parts, become diminished, whilst

the condensation of the vapour might augment parts less exposed, and situated nearer to the body of the planet: and these conditions might continue, until at last the ring itself was melted or partially melted through at one or more points, and the whole might break up, and the fragments moving in a resisting medium, would ultimately fall down on the surface of the planet. The tearing up of that surface from such an event, would be augmented by the sudden conversion of the solid ice into steam; and after a time, the fragments of the ring would be absorbed again into the atmosphere of the planet.

Let us now suppose, owing to the gradual cooling down of the whole globe, the limit of condensation of steam into water, to occur at a nearer point than that at which the centrifugal force equals that of gravity. As soon as the steam is condensed into water, it will descend towards the surface of the earth; but that surface being still very hot, will, by its radiation, again convert the descending shower into steam; and this will happen at different heights above the surface, according to the radiating power of the part below. We may, therefore, conceive a shell surrounding the earth, the outer surface of which has just been condensed into water, and the inner consists of vapour, just re-converted into that state by the earth's radiation. These surfaces will attain different heights in different places. Between these two surfaces there will exist a perpetual

rain, descending from the upper as a gentle shower, becoming gradually a violent torrent, and then as it falls re-absorbed into another gentle shower, which is entirely converted into vapour in approaching the heated surface.

Such being the state of things, let us imagine the globe to cool down uniformly. The lower surface of the descending rain, which is placed at irregular heights, will at length be brought down to the earth's surface in one or more points. The effect of this, which will in the first instance be a gentle shower, would be to cool that portion of the surface on which it falls, and hence to diminish its radiating power. This change, in its turn, will lower the under surface of the watery shell, so that a more violent rain, and ultimately an impetuous torrent will continue, perhaps, for thousands of years, its unremitted vertical action on the surface exposed to its force. The excavation of the largest valleys, or even of ocean beds, is not too much to expect from such forces.

But let us take another view of the consequences of such an original state of incandescence. The whole of the fluids now on the surface of the earth must then have been suspended in its atmosphere. But the extent of that atmosphere is itself limited by various causes: the attraction of other bodies, the effects of centrifugal force, the decrease of temperature, and the

distances at which the particles of gaseous bodies cease to repel each other, all have their influence in determining its form and magnitude. Let us suppose that we possessed data from which the approximate amount of vapour contained in the entire atmosphere were known, and consequently the whole quantity of water in it; then, since we know the area of the present seas, we might easily ascertain their average depth. If the result of such a computation should give a mean depth much less than that which we know the ocean to possess,—as, for instance, only a hundred feet,—then we might conclude, either that the surface of the earth had never been in such a state of incandescence as has been supposed, or if it had, that a new source of aqueous vapour had been supplied to it, subsequently to its cooling down.

NOTE G.

ON THE ACTION OF EXISTING CAUSES IN PRODUCING
ELEVATIONS AND SUBSIDENCES IN PORTIONS OF
THE EARTH'S SURFACE.

THE following explanation of the origin of many of the changes at present going on on the earth's surface, was suggested in endeavouring to account for the very singular phenomena presented by the temple of Jupiter Serapis, at Puzzuoli, near Naples. The facts relating to that temple were observed by me in 1828, and the theory occurred soon after my return to England; but though occasionally mentioned to geological friends, it was not printed until it appeared in the abstract of my paper on the Temple of Serapis, presented to the Geological Society of London, in March 1834.

The following positions are taken as the basis of the reasoning on this subject:—

1. That, as we descend below the surface of the earth, the temperature increases.

2. That solid rocks expand by being heated; but that clay, and some other substances, contract under the same circumstances.

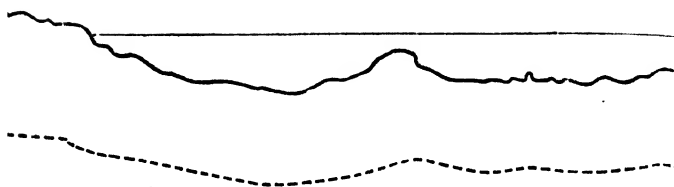

3. That different rocks and strata conduct heat differently.

4. That the earth radiates heat differently, at different parts of its surface, according as it is covered with forests, with mountains, with deserts, or with water.

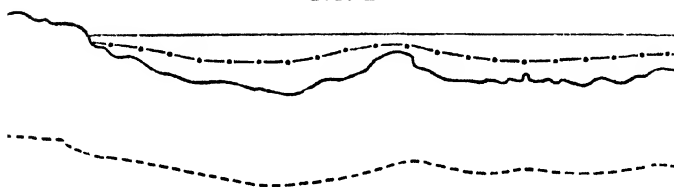

5. That existing atmospheric agents, and other causes, are constantly changing the condition of the surface of the globe.

The only one of these propositions on which, in the present state of knowledge, the slightest question can be raised, is the first. But the observations on which it depends have latterly become so numerous, that the general fact of an increase of temperature, in descending through the crust of the earth, can scarcely be questioned; although the exact law of this increase, and the extent to which it penetrates, are yet undecided.

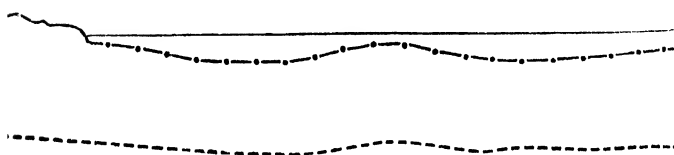

An increase of 1° Fahrenheit's thermometer, for every 50 or 60 feet we penetrate below the earth's surface,

No. 2.

No. 4.

seems nearly the average result of observations. If the rate continue, it is obvious that, at a small distance below the surface, we shall arrive at a heat which will keep all the substances with which we are acquainted in a state of fusion. Without, however, assuming the fluidity of the *central* nucleus,—a question yet unsettled, and which rests on very inferior evidence* to that by which the principles here employed are supported,—we may yet arrive at important conclusions; and these may be applied to the case of central fluidity, according to the opinions of the inquirer.

If we consider the temperature of any point:—for example, G, situated two miles below the surface of an elevated table land, A, in the annexed wood-cut; and if we imagine a surface passing through all the points of equal temperature within the globe; then, as this surface passes under the adjacent ocean, which we may suppose, on an average, to be two miles deep, it is evident that the *surface of equal heat* will descend towards the earth's centre; because, if it did not, we should have great heat nearly in contact with the bottom of the sea. In the first figure, B is the surface of the ocean. A D, the surface of the land, and of the bed of the ocean. The broken line, G F, is the isothermal line. Let us now

* The reader will find this question fully discussed in the 17th chapter of Lyell's *Geology*; On the Causes of Earthquakes and Volcanoes.

suppose, by the continual wearing down of the continents and islands adjoining this ocean, that it becomes nearly filled up. The broken line C, in the second figure of the wood-cut, indicates the new bottom. The former bottom of the ocean being now covered with a bad conductor of heat, instead of with a fluid which rapidly conveyed it away, the surface of uniform temperature will rise, slowly but considerably, as is shown at G E, in the third figure. In the fourth figure, the first bed of the ocean, A D, and its isothermal line, G F, as well as the new bed, A C, of the ocean, and its corresponding isothermal line, G E, are all shown at one view.

The newly formed strata will be consolidated by the application of heat; they may, perhaps, contract in bulk, and thus give space for new deposits, which will, in their turn, become similarly consolidated. But the surface of uniform temperature below the bed of the ocean cannot rise towards the earth's surface, without an increase in the temperature of all the beds of various rock on which it rests; and this increase must take place for a considerable depth. The consequence must be a gradual rise of the ancient bed of the ocean, and of all the deposits newly formed upon it. The shallowness of this altered ocean will, by exposing it to greater evaporation from the effect of the sun's heat, give increased force to the atmospheric causes still operating upon

the inequalities of the solid surface, and tend more rapidly to fill up the depressions.

Possibly the conducting power of the heated rocks may be so slow, that its total effect may not be produced for centuries after the sea has given place to dry land; and we can conceive, that in such circumstances,—the force of the sun's rays from without, and the increasing heat from below, so consolidating the surface, that the land may again descend below the level of adjacent seas, even though its first bottom is still subject to the elevatory process. Thus, a series of shallow seas or large lakes might be formed; and these processes might even be repeated several times, before the full effect of the expansion from below had permanently raised the whole newly-formed land above the influence of the adjacent seas.

If the sea were originally much deeper, or, if in particular parts it were much deeper, as, for instance, ten or twenty miles, then a portion of the solid matter beneath its surface might, after the lapse of many ages, acquire a red, or even a melting heat, and the conversion into gases of some of the substances thus operated on, might give rise to earthquakes, or to subterraneous volcanoes.

On the other hand, as the high land gradually wears away, by the removal of a portion of its thickness, and

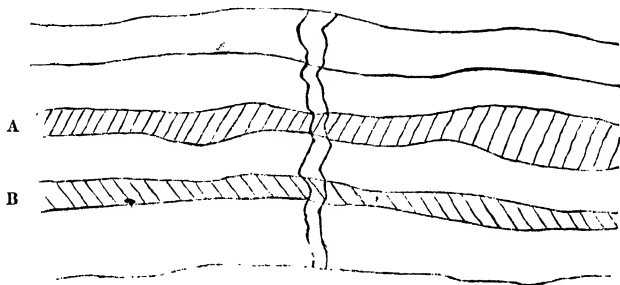

as the cooling down of its surface takes place, its contraction might give rise to enormous rents. If these cracks penetrate to any great reservoirs of melted matter, such as appear to subsist beneath volcanoes, then they will be compressed by the contraction, and the melted matter will rise and fill the cracks, which, when cooled down, will become dykes.

If these rents do not reach the internal reservoir of melted matter, and if there exist in the neighbourhood any volcanic vents connected with it, the contraction of the upper strata may give rise to volcanic eruptions, through those vents, which might be driven by such a force to almost any height. These eruptions may themselves diminish the heat of the beds immediately above the melting cauldron from which they arise; for the conversion of some of the fluid substances into gases, on the removal of the enormous pressure, will rapidly abstract heat from the melted mass.

As the removal of the upper surface of the high land will diminish its resistance to fracture, so the altered pressure arising from the removal of that weight, and its transfer to the bottom of the ocean, may determine the exit of the melted matter.

Other consequences might arise from the different fusibility of the various strata deposited in the bed of the ocean. Let us imagine, in the annexed wood cut,

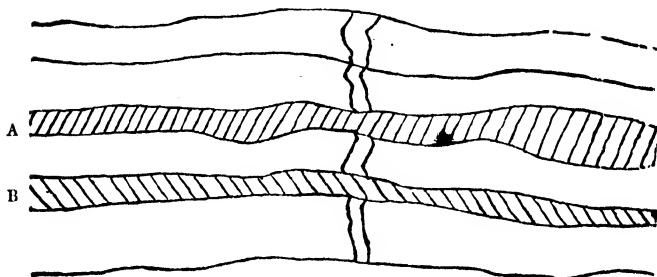

the two beds, A and B, to melt at a much lower temperature than those between which they intervene. It might happen, by the gradual rising of the isothermal surfaces, that one or both of those strata should be

melted; and thus, supposing all the beds originally to have contained marine remains, we might, at a distant period, discover two interposed beds, without any trace of such remains, but presenting all the appearances of former fusion, resting on, separated by, and existing under, other beds of demonstrably marine formation.

If, during that former state of fusion, rents should have been formed through several of the strata, injection of the liquid matter might proceed from these melted beds, both upwards and downwards. If, on the contrary, older dykes had penetrated all the strata, it is possible to suppose such a degree of fusibility in the older dyke, or such chemical relation to the melted bed, that the portions of the dyke passing through that bed shall be obliterated, whilst those which traverse

the less fusible beds, protected from such action, shall remain unaltered, as in the annexed cut.

Another consequence of this constant change in the position of the isothermal surfaces must be the development of thermo-electricity, which, acting on an immense scale, may determine the melting of some beds, or the combination of the melted masses of others, or cause the segregation of veins and crystals, in heated, though not fluid, portions of the strata exposed to its influence. Nor may the dykes themselves be without their use, either in keeping up the communication for the passage of electricity, if they are good conductors, —or in separating the groups of strata which produce it, if they are bad conductors.

For the elucidation of this subject, it appears very important that experiment should be made on the effects of long-continued artificial heat in altering and obliterating the traces of organic remains existing in known rocks. It seems probable that by a well-planned series of such experiments, we might be enabled to

trace the gradually disappearing structure of animal remains existing in rocks subjected to fire, into marks which, without such aid, seem utterly distinct from that origin; and that we might thus establish new alphabets with which to attempt the deciphering of some of the older rocks.*

It appears, therefore, that from changes continually going on, by the destruction of forests, the filling up of seas, the wearing down of elevated lands,—the heat radiated from the earth's surface varies considerably at different periods. In consequence of this variation, and also in consequence of the covering up of the bottoms of seas, by the detritus of the land, the *surfaces of equal temperature* within the earth are continually changing their form, and exposing thick beds near the exterior to alterations of temperature. The expansion and contraction of these strata may form rents and veins, produce earthquakes, determine volcanic eruptions, elevate continents, and possibly raise mountain chains.

The further consequences resulting from the working out of this theory would fill a volume, rather than a note.

* Some experiments, with this object in view, were undertaken at the recommendation of the British Association, (See Third Report, p. 479, and Fourth Report, p. 576.) and portions of rock, containing organic remains, have already (1838) been exposed, for above five years, to the heat of the hearth of a blast furnace, at the Elsecar iron works in Yorkshire, through the permission of Earl Fitzwilliam, and at the Low Moor works, by that of the proprietors.

It may, however, be remarked, that whilst the principles on which it is founded are really existing causes, yet that the sufficiency of the theory for explaining all the phenomena cannot be admitted until it shall have been shown, that their power is fully adequate to produce all the observed effects.

TABLE

Showing the Expansion of Beds of Granite variously heated, from One Degree to One Hundred Degrees Fahrenheit, and from One to Five Hundred Miles thick.

500	2547·5	6369·0	12738·0	38214·0

The table was calculated from experiments made under the direction of Colonel Totten, by Mr. H. C. Bartlett, of the United States Engineers; an account of which is given in the *American Journal of Science*, Vol. XXII. p. 136.

From the result of these experiments it was found that, for every degree of Fahrenheit,

Granite expands	·000004825
Marble	·000005668
Sandstone	·000009532

The tables were computed by the Calculating Engine, from the first line, which was deduced from the experiment. It will be observed that the numbers given are always true to the last figure, a compensation which the Engine itself made. In order to find the expansion for marble, increase the numbers by one-sixth. To find the expansion for sandstone, double the numbers found in the table.

Other experiments have since been made by Mr. Adie, of which an account is given in the thirteenth volume of the *Transactions of the Royal Society of Edinburgh*: from these I have selected the following list of expansions :—

Roman Cement expands	·00000750
Sicilian White Marble	·00000613
Carrara Marble	·00000363

Sandstone, from Craigleith quarry	·00000652
Slate, from Penrhyn, Wales	·00000576
Peterhead Red Granite	·00000498
Arbroath Pavement.	·00000499
Caithness Pavement.	·00000497
Greenstone, from Ratho	·00000449
Aberdeen Grey Granite	·00000438
Best Stock Brick	·00000306
Fire Brick	·00000274
Black Marble, Galway	·00000247

NOTE I.

I AM happy to be enabled to put before the reader extracts from two letters of Sir J. Herschel, which show, that though my early friend is extending the boundaries of our system, by his observations in the southern hemisphere, his active and indefatigable mind has yet found time to throw its comprehensive glance over some of the highest questions which perplex other sciences. I feel, that the almost perfect coincidence of his views with my own, gives additional support to the explanations I have offered; whilst the reader will perceive, from the different light in which my friend has viewed the subject, that we were both independently led to the same inferences by different courses of inquiry. ~

I. The first of the letters to which I allude, and of which I shall extract the greater part, is addressed to Mr. Lyell.

“ Feldhausen, Cape of Good Hope, Feb. 20, 1836.

“ MY DEAR SIR,

“ I am perfectly ashamed not to have long since acknowledged your present of the new edition of your

“ Geology, a work which I now read for the third
 “ time, and every time with increased interest, as it
 “ appears to me one of those productions which work
 “ a complete revolution in their subject, by altering
 “ entirely the point of view in which it must thence-
 “ forward be contemplated. You have succeeded, too,
 “ in adding dignity to a subject already grand, by ex-
 “ posing to view the immense extent and complication
 “ of the problems it offers for solution, and by unveiling
 “ a dim glimpse of a region of speculation connected
 “ with it, where it seems impossible to venture without
 “ experiencing some degree of that mysterious awe
 “ which the sybil appeals to, in the bosom of Æneas,
 “ on entering the confines of the shades—or what the
 “ Maid of Avenel suggests to Halbert Glendinning,

‘ He that on such quest would go, must know nor fear nor failing;
 To coward soul or faithless heart the search were unavailing.’

“ Of course I allude to that mystery of mysteries, the
 “ replacement of extinct species by others. Many
 “ will doubtless think your speculations too bold, but
 “ it is as well to face the difficulty at once. For my
 “ own part, I cannot but think it an inadequate con-
 “ ception of the Creator, to assume it as granted that
 “ his combinations are exhausted upon any one of the
 “ theatres of their former exercise, though in this, as
 “ in all his other works, we are led, by all analogy, to
 “ suppose that he operates through a series of inter-
 “ mediate causes, and that in consequence the origina-

“ tion of fresh species, could it ever come under our
 “ cognizance, would be found to be a natural in con-
 “ tradistinction to a miraculous process—although we
 “ perceive no indications of any process actually
 “ in progress which is likely to issue in such a
 “ result.”

— — — — —
 — — — — —
 — — — — —

“ Now for a bit of theory. Has it ever occurred to
 “ you to speculate on the probable effect of the trans-
 “ fer of pressure from one part to another of the earth’s
 “ surface by the degradation of existing and the for-
 “ mation of new continents—on the fluid or semi-fluid
 “ matter beneath the outer crust? Supposing the
 “ whole to float on a sea of lava, the effect would
 “ merely be an almost infinitely minute flexure of the
 “ strata; but, supposing the layer next below the
 “ crust to be partly solid and partly fluid, and com-
 “ posed of a mixture of fixed rock, liquid lava, and
 “ other masses, in various degrees of viscosity and
 “ mobility, great inequalities may subsist in the dis-
 “ tribution of pressure, and the consequence may be,
 “ local disruptions of the crust, where weakest, and
 “ escape to the surface of lava, &c. If the obstructions
 “ to free communication among distant parts of a fluid
 “ be great, no *instantaneous* propagation of pressure

“ can subsist, the hydrostatical law of the equality of
“ pressure being only true of fluids in a state of un-
“ disturbed equilibrium. If the whole contents of the
“ fissures, pipes, &c., into which we may consider the
“ interior divided, were lava, it is true no increase of
“ pressure on the bed of an ocean, from deposited
“ matter, could force the lava up to a higher level than
“ the surface, or so high. But if the contents be
“ partly liquid, partly gaseous, or partly water, in a
“ state to become steam, at a diminished pressure,
“ then it may happen that the joint specific gravity of
“ lava + gas, or lava + steam occupying any given chan-
“ nel may be less than that of water; or of the joint
“ column of water + newly deposited matter—which
“ may be brought to press upon it by any sudden giving
“ way of support, and the effect will be the escape of
“ a mixture of lava and gas, either together, as froth
“ and pumice, or by fits, according as they are disposed
“ in the channel. This (taken as a general cause of
“ volcanoes) would account for the great quantity of
“ gaseous matter which always accompanies eruptions,
“ and for the final *blow out* of wind and dust with
“ which they so often terminate. It has always been
“ my greatest difficulty in Geology to find a *primum*
“ *mobile* for the volcano, taken as a general, not a
“ local phenomenon. Davy’s speculations about the
“ oxidation of the alkaline metals seems to me a mere
“ chemical dream, and the fermentation of water and
“ pyrites as utterly insignificant on a scale of any

“ magnitude. Poulett Scrope’s notion of solid rocks
 “ flashing out into lava and vapour, on *removal of*
 “ *pressure*, and your statement of the probable cause of
 “ Volcanic Eruptions, in p. 385, vol. ii. 4th Ed. when
 “ you speak of the effect of a minute hole bored in a
 “ tube, in which liquefied gases are imprisoned, both
 “ appear to me wanting in explicitness, and as not going
 “ high enough in the inquiry, up to its true beginning,
 “ and also as giving, in some respects, a wrong notion
 “ of the process itself. The question stares us in the
 “ face—How came the gases to be so condensed?
 “ Why did they submit to be urged into liquefac-
 “ tion? If they were not originally elastic, but have
 “ become so by subterranean heat, whence came
 “ the heat? and *why did it come?* How came the
 “ pressure to be removed, or what caused the crack?
 “ &c. &c.

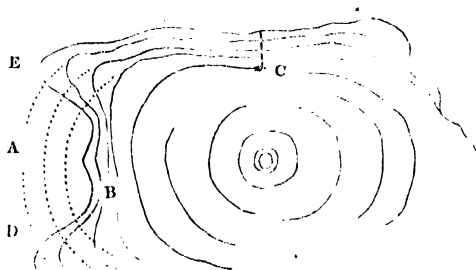

“ It seems clear that if the gases, or aqueous vapour,
 “ were once free, at so high a degree of elasticity as
 “ is presumed, there exists no adequate cause for their
 “ confinement,—the spring once uncoiled, there is
 “ nowhere a power capable of bending it up to the
 “ pitch. We are forced therefore to admit, that the
 “ elastic force has been superadded to them, during
 “ their sojourn below, by an accession of temperature.
 “ Now, though I cannot agree with you in your view
 “ of the subject of the Central heat, p. 373, vol. ii. 4th
 “ Ed. (because I see no reason why the heat may not

“ go on increasing *to the very centre* without necessitat-
 “ ing such disturbance of equilibrium as to give rise to
 “ any circulation of currents, which you there seem to
 “ regard as the necessary consequence of such a state*),
 “ yet I agree entirely with what you observe in p. 376,
 “ —that the ordinary repose of the surface argues a
 “ wonderful inertness in the interior, where, in fact,
 “ I conceive that every thing is motionless. Under
 “ these circumstances, and debarred from that obvious
 “ means of boiling our pot, the invasion of a circulat-
 “ ing current, or casual injection of intensely hot
 “ liquid matter from below, the question, ‘ *Whence*
 “ *comes the heat?*’ and ‘ *Why did it come?*’ remains
 “ to be answered on sound theoretical grounds. Now,
 “ the answer I conceive to be as follows:—

“ Granting an equilibrium of temperature and pres-
 “ sure within the globe, the isothermal strata near
 “ the centre will be spherical, but where they approach
 “ the surface will, by degrees, conform themselves to
 “ the configuration of the *solid* portion; that is, to the
 “ bottom of the sea and the surface of continents.
 “ Suppose such a state of equilibrium, and that under

* “ Heated liquids circulate not because the lower parts are *hotter*, but
 “ because they are *lighter*, than the upper. But in the interior of a
 “ heated globe, the density depends not only on the temperature, but
 “ on the *pressure* (i. e. the depth) of each stratum; so that nothing is
 “ easier than to imagine a law of increasing temperature which shall
 “ co-exist with increasing density.

“ the bottom B of my great ocean D E, the isother-
 “ mal strata are as represented by the black lines.

“ Now, let that basin be filled with solid matter up to
 “ A. Immediately the equilibrium of temperature
 “ will be disturbed. Why?—because the form of a
 “ stratum of temperature depends essentially on the
 “ form of the bounding surface of the solid above it,
 “ that form being one of the arbitrary functions which
 “ enter into its partial differential equation. Im-
 “ mediately, therefore, the temperature will begin to
 “ migrate from below upwards, and the isothermal
 “ strata will gradually change their forms from the
 “ black to the dotted lines. The lowest portions at
 “ B will then (after the lapse of ages, and when a
 “ fresh state of equilibrium is attained) have acquired
 “ the temperature of the stratum C, corresponding
 “ to *their then* actual depth, while a point as deep
 “ below B as C is below the surface, will have

“ acquired a much higher temperature, and *may become*
“ *actually melted, and that without any bodily transfer*
“ *of matter in a liquid state from below.* But if C be
“ already at the melting point, B will now be so—
“ i. e. the lower level will attain B, and the bottom of
“ the new strata will melt, *water included*, with which,
“ from the circumstances of the case, they must be
“ saturated.

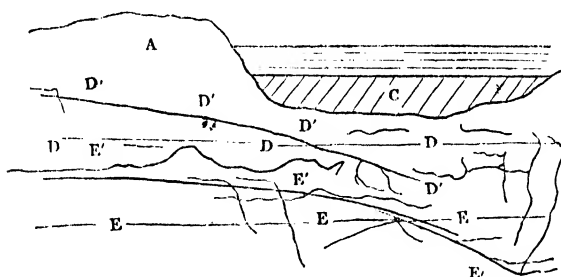

“ Now, let the process of deposition go on, until,
“ by accumulation of pressure on the bottom or sloping
“ sides, or on some protuberance from the bottom,
“ some support gives way—a piece of the solid crust
“ breaks down, and is plunged into the liquid below,
“ and a crack takes place extending upwards. Into
“ this the liquid will rise by simple hydrostatic pres-
“ sure. But as it gains height, it is less pressed; and
“ if it attain such a height that the ignited water can
“ become steam, the case before alluded to arises, the
“ joint specific gravity of the column is suddenly
“ diminished, and up comes a jet of mixed steam and
“ lava, till so much has escaped that the deposited
“ matter takes a fresh bearing, when the evacuation
“ ceases, and the crack becomes sealed up.

“ In the analysis I have above given of the process
“ of heating from below, we have, if I mistake not, a
“ strictly theoretical account of that great desidera-
“ tum of the Huttonian theory—‘Let heat,’ says he,

“ ‘invade a newly deposited stratum from below.’—
“ But why? Not because great currents of melted
“ matter are circulating in the nucleus of the globe—
“ not because great waves of caloric are rushing to and
“ fro, without a law and without a cause in the subter-
“ ranean regions—but simply because the fact of new
“ strata *having* been deposited, alters the conditions of
“ the equilibrium of temperature, and they draw the
“ heat to them, or, which comes to the same thing,
“ retain it *in* them in its transit outwards (the supply
“ from the centre being supposed inexhaustible, and
“ its temperature of course invariable).

“ According to the general tenor of your book, we
“ may conclude, that the greatest transfer of material to
“ the bottom of the ocean, is produced at the coast line
“ by the action of the sea; and that the quantity carried
“ down by rivers from the surface of continents, is
“ comparatively trifling. While, therefore, the greatest
“ local accumulation of pressure is in the central area
“ of deep seas, the *greatest local relief* takes place along
“ the abraded coast lines. Here, then, in this view,
“ should occur the chief volcanic vents. If the view
“ I have taken of the motionless state of the interior
“ of the earth be correct, there appears no reason why
“ any such influx of heat should take place under an
“ existing continent (say Scandinavia) as to heat incum-
“ bent rocks (whose bases retain their level) 5 or 600°
“ Fahr. for many miles in thickness. (Princ. of Geol.

“ vol. ii. p. 384. 4th Ed.) Laplace’s* idea of the elevation
 “ of surface due to columnar expansion (which you at-
 “ tribute, in a note, to Babbage,) is in this view in-
 “ adequate to explain the rise of Scandinavia, or of
 “ the Andes, &c. But, in the variation of local pres-
 “ sure due to the transfer of matter by the sea, on the
 “ bed of an ocean imperfectly and unequally support-
 “ ed, it seems to me an adequate cause may be found.
 “ Let A be Scandinavia, B the adjacent ocean (the North
 “ Sea), C a vast deposit, newly laid on the original bed
 “ D of the ocean; E E E a semi-fluid, or mixed

“ mass, on which D D D reposes. What will be the
 “ effect of the enormous weight thus added to the bed
 “ DDD (rock being heavier than sea)? Of course,

* “ Nisi Mitscherlich’s. I remember well to have read it somewhere or other.”

[This was written before my friend had received the abstract of the Paper on the Temple of Serapis, forwarded to him by Mr. Lyell. The reader will perceive, by Note G. of the Appendix, that *isothermal surfaces* form the prominent feature of both our views of this question.— C. B.]

“ to depress D under it, and to force it down into the
 “ yielding mass E, a portion of which will be driven
 “ laterally under the continent A, and upheave it.
 “ Lay a weight on a surface of soft clay: you depress
 “ it below, and raise it around the weight. If the
 “ surface of the clay be dry and hard, it will crack in
 “ the change of figure.”

“ I don't know whether I have made clear to you
 “ my notions about the effects of the removal of mat-
 “ ter from above, to below, the sea. 1st. It produces
 “ a mechanical subversion of the *equilibrium of pres-*
 “ *sure.* 2dly. It also, and by a different process (as
 “ above explained at large), produces a subversion of
 “ the equilibrium of temperature. The last is the most
 “ important. *It must be an excessively slow process,*
 “ and will depend, 1st, on the depth of matter depo-
 “ sited; 2dly, on the quantity of water retained by it
 “ under the great squeeze it has got; 3dly, on the
 “ tenacity of the incumbent mass—whether the influx
 “ of caloric from below, WHICH MUST TAKE PLACE,
 “ acting on that water, shall either heave up the whole
 “ mass, as a continent, or shall crack it, and escape
 “ as a submarine volcano, or shall be suppressed
 “ until the mere weight of the continually accumulat-
 “ ing mass breaks its lateral supports at or near the
 “ coast lines, and opens there a chain of volcanoes.

“ Thus the circuit is kept up—the *primum mobile*
“ is the degrading power of the sea and rains (both
“ originating in the sun’s action) above, and the
“ inexhaustible supply of heat from the enormous
“ reservoirs below, always escaping at the surface, un-
“ less when repressed by an addition of fresh clothing,
“ at any particular part. In this view of the subject,
“ the *tendency is outwards*. Every continent deposited
“ has a propensity to rise again; and the destructive
“ principle is continually counterbalanced by a re-or-
“ ganizing principle from beneath. Nay, it may go
“ farther—there may be such a tendency in the globe
“ to swell into froth at its surface, as may maintain its
“ dimensions in spite of its expense of heat; and thus
“ preserve the uniformity of its rotation on its axis, in
“ spite of the doctrines of refrigeration and contrac-
“ tion, (which, by the bye, had occurred to myself,
“ and been rejected, as inadequate to give a general
“ formula of explanation of volcanoes, &c.) Perhaps
“ I shall recur to this subject on some future occa-
“ sion; but really the stars leave me very little time
“ to lick into form any geological theories, or even
“ to examine them with any degree of scrupulous
“ severity.”

II. The following is the copy of a letter from Sir John Herschel to Mr. Murchison, in explanation of the views expressed in his previous letter to Mr. Lyell.

“Feldhausen, Cape of Good Hope, Nov. 15, 1836.

“ In the letter you allude to as having been written
“ by me to Mr. Lyell, there were some speculations
“ about the effect of central heat on newly-deposited
“ matter, which, judging from some expressions in his
“ answer to that letter, I am inclined to think must
“ have been put obscurely, since he appears disposed
“ to regard the view I took of the subject as identical
“ with some theory ascribed to Mr. Babbage (but, I
“ believe, before propounded by Mitscherlich) about
“ the elevation of strata by *pyrometric expansion* of the
“ subjacent columns of rock, by an invasion of subter-
“ raneous heat. *Granting the heat*, there is no difficulty
“ in deducing expansions, disruptions, tumefactions,
“ &c. ; but *this* was not my drift. Will it be tres-
“ passing too much on your patience if I here state, in
“ brief, what I really had in view—which, so far as I
“ can recollect, has not hitherto been duly, or not at
“ all, considered? If you like to call it my ‘theory,’
“ you may do so ; but it is not so much ‘a theory,’ as a
“ pursuing into its consequences, according to admitted
“ laws, of the hypothesis of a high central tempera-
“ ture, which many geologists admit, and all are fa-
“ miliar with.

“ Granting, then, as a postulate, a gradation of
“ temperature within the globe, from the observed ex-
“ ternal temperature at the surface, up to a high state

“ of incandescence at the centre : I say, that when solid
“ matter comes to be deposited to any considerable
“ thickness on any part of the bed of the ocean, by sub-
“ sidence, (or even on the surface of a continent, by
“ volcanic ejection, as in great volcanic plateaux and
“ table-lands, or by the action of the wind, as in sand
“ hills,) the mere fact of such accession of materials,
“ *without requiring any other condition, or concomitant*
“ *cause*, will, of itself, in virtue of the known laws of
“ the propagation of heat through a slowly-conducting
“ mass, immediately subvert the equilibrium of tem-
“ perature, and induce a change in the form of the
“ isothermal surfaces (curves of equal temperature) in
“ the whole region immediately beneath, and surround-
“ ing the point of deposition—causing all those surfaces
“ (which, you will observe, are only imaginary mathe-
“ matical ones, like lines of equal variation in a mag-
“ netic chart—not real strata) to bulge outwards, and
“ recede from the centre in that part. The direct con-
“ sequence of this will be, that any given point of the
“ surface on which the deposit took place will, when a
“ new state of equilibrium is attained, (supposing it to
“ be so) have a temperature corresponding to an iso-
“ thermal surface *of a deeper order* : i. e., it will have
“ become hotter than it was previous to the new de-
“ posit ; and the same is true of every point in the
“ vertical line drawn from that point downwards. Sup-
“ posing, as before said, a new state of equilibrium to
“ be attained, (the deposition ceasing, by the filling up

“ of the sea in that part) then the temperature of the
“ lowest parts of the newly-formed strata will be that
“ of a point situated beneath the surface of an old con-
“ tinent in the same latitude, at a depth equal to the
“ thickness of the deposited matter. The thicker, there-
“ fore, the deposit, the hotter will its lower portions
“ tend to grow; and, if thick enough, they may grow
“ red hot, or *even melt*. In the latter case, their supports
“ being also melted or softened, may wholly or partially
“ yield, *under the new circumstances of pressure*, to
“ which they were originally not adjusted; and the
“ phenomena of earthquakes, volcanic explosions, &c.,
“ may arrive—while, on the other hand, if no cracks
“ occur, and all goes on in quiet, the only consequence
“ will be, the obliteration of organic remains, and lines
“ of stratification, &c.—the formation of new combina-
“ tions of a chemical nature, &c. &c.—in a word, the
“ production of Lyell’s ‘metamorphic’ rocks.

“ The process described above is precisely that by
“ which a man’s skin grows warmer in a winter day by
“ putting on an additional great coat; the flow of heat
“ outwards is obstructed, and the surface of congela-
“ tion carried to a distance from his person, by the
“ accumulation of heat thereby caused beneath by the
“ new covering.

“ You see, therefore, that my object is to get at a
“ geological ‘*primum mobile*,’ in the nature of a *vera*

“ *causa*, and to trace its working in a distinct and in-
 “ telligible manner. In future, therefore, instead of
 “ saying, as heretofore, ‘*Let heat from below invade*
 “ newly-deposited strata (Heaven knows how or why),
 “ then they will melt, expand,’ &c. &c., we shall
 “ commence a step higher, and say, ‘*Let strata be*
 “ *deposited.*’ Then, as a necessary consequence, and
 “ according to known, regular, and calculable laws, heat
 “ *will* gradually invade them from below and around;
 “ and, according to its due degree of intensity at any
 “ assigned time, will expand, ignite, or melt them,
 “ as the case may be, &c. &c. &c.; and, I mistake
 “ greatly, if this be not a considerable reform in our
 “ geological language.

“ According to this view of the matter, there is no-
 “ thing casual in the formation of Metamorphic Rocks.
 “ All strata, once buried deep enough, (and due TIME
 “ allowed!!!) must assume that state,—none can
 “ escape. All records of former worlds must ulti-
 “ mately perish.

“ P.S.—If you think it worth while to read the above
 “ speculation whenever a discussion may arise, natu-
 “ rally leading to it, at any meeting of the Geological
 “ Society, (not as a formal communication, for I have
 “ not time to put it into shape, or work it out in detail,
 “ but incidentally) you are quite at liberty to do so;
 “ and I shall be glad to know your own opinion of it.”

Since the first edition of this work was published, Mr. Lyell has received another letter from Sir John Herschel, explanatory of his views on this subject; and I am happy to place before the reader the following extracts, not because there is any necessity to prove that my friend arrived independently at the same conclusions with myself, but because they afford additional illustrations of a view which we both think deserving of further inquiry.

This letter was written by Sir John Herschel previously to the receipt of the first edition of this volume, which I had forwarded to him at the Cape of Good Hope.

“Feldhausen, June 12, 1837.

* * * * *

“I reply to your note, however, immediately, “because there are points in it, and in a letter of “Murchison’s I lately received, but especially in “yours, which call for immediate notice on my part, “lest I should be supposed to have willingly and “knowingly, what our French neighbours call, “‘emprunté des idées,’—appropriated the ideas of “Babbage; to which charge should any one feel “disposed to bring it (B. I am sure will not), I plead “not guilty. Till the arrival of Murchison’s letter, “in fact, I was utterly unaware that Babbage had (or “any body else) speculated on that peculiar mutual

“ reaction of the surface and interior of the globe,
“ which consists in what, I think, we must now call
“ ‘ the secular variation of the isothermal surfaces ’ of
“ the latter. The idea I considered as entirely my
“ own ; and I was never more taken by surprise, than
“ when to-day, directed for the first time by an
“ express mention in your letter of a paper of Bab-
“ bage’s, abstracted in the Geological Notices, I
“ hunted up all those notices in my possession, and
“ found in an uncut Number (No. 36,)—as I am
“ sorry to say many of these, and other not less inte-
“ resting brochures which have reached me, still are—
“ an abstract of a paper on the Temple of Serapis, at
“ the end of which a theory identical with mine in
“ that leading point, undoubtedly stands printed.

“ Convinced as I feel of the great importance of
“ this general view of geological revolutions, in
“ contrast with all the arbitrary, local, and temporary
“ expedients which have hitherto been resorted to to
“ explain particular phenomena, and to the recourse
“ had to ‘ the volcano and the earthquake,’ as the
“ great explaining powers ; whereas in this view,
“ these are only symptomatic phenomena, natural and
“ necessary concomitants of systems of action much
“ more extensive, which are constantly going forwards.
“ ...But as I do, at all events, lay claim to absolute
“ independence of speculation on the subject, it is
“ quite right that I should make clear to you and to

“ him the progress of my own ideas, and also account
 “ for what must have appeared singular in my own
 “ mention of his speculations in my letter to Murchison.
 “ And to take the last first:—The fact is, that I never
 “ was aware that Babbage had made *any* communi-
 “ cation to the Geological Society on the subject, till
 “ Murchison’s letter first led me to suppose, and
 “ yours expressly stated, by referring to the Pro-
 “ ceedings for an abstract, that such was the case.
 “ The passage in your book and note appended,
 “ (Vol. II. p. 383, 4th Edit.) contain no allusion to
 “ the *cause* of rocks becoming heated from below.
 “ The employment of the pyrometric expansion of
 “ rocks as a motive power, was, I feel confident,
 “ suggested by *some* one (and the name of Mitscherlich
 “ or Laplace, has somehow got connected in my
 “ memory with it) many years ago, certainly before
 “ 1833. Of this B. must have been as ignorant as I
 “ was of his views, as he appears to have based his
 “ ideas on Colonel Tottens’* experiments (when made
 “ I know not). And I only remembered to have read
 “ Babbage’s paper on the Temple of Serapis, pub-
 “ lished in one of the quarterly journals not long after
 “ his arrival from the Continent, in which, so far as I
 “ recollect, this point is not touched upon; nor is it in
 “ your speech from the chair, where alternate pyro-
 “ metric expansion and contraction, without reference

* The origin of my view is stated in the first paragraph of this Note.

“ to the cause of the invasion or abstraction of heat,
“ are alone alluded to.

“ However, discussion of points of this sort is of
“ little moment in itself; as, if a theory be founded in
“ sound views, it matters little to the world whether
“ A. or B. or A. and B. first entertained it, or whether
“ it arose in the whole alphabet when its seeds were
“ ready to germinate. As regards the course of my
“ own ideas, it was simply this. When I first read
“ your book, I was struck with your views of the
“ metamorphic rocks, and I began to speculate how
“ and why the mere fact of deep burial might tend to
“ raise their temperature to the required point. Three
“ modes occurred :—1st. Development of heat by con-
“ densation ; but this cause seemed somewhat feeble,
“ and not very clear in its mode of action, since at
“ every moment an equilibrium of pressure and
“ resistance is established. 2dly. Plunging down
“ into an ignited pasty mass ; here however, consi-
“ dering the excessive slowness of the process, it
“ occurred to me that there would be plenty of time
“ for the ignited matter below, not merely to divide its
“ caloric with the newly superposed mass, but to take
“ up fresh from below, and thus to establish a regular
“ gradation of temperature from below upwards. And
“ this led to the 3d and more general view of the matter,
“ which is that of the variation of isothermal surfaces,
“ as stated in my letters to Murchison and yourself.

“ These notions had been fermenting and regur-
“ gitating in the cavities of my brain, from the moment
“ I first read your statement of the metamorphic
“ doctrine in your first edition ; but what determined
“ the disruption of the incumbent stratum, and their
“ final explosion, was the reperusal of your little 12mo.
“ edition you were so good as to send me.

“ All things considered, however, I do not regret
“ having written what I did : and I am still so far
“ disposed to regard it as *publici juris*, as to wish that
“ such passages in my letters as yourself and Mur-
“ chison may think eligible for the purpose, might on
“ some fitting opportunity be read at a meeting of the
“ Geological Society. (All idea of my drawing up a
“ regular paper is out of the question, I am so in-
“ volved in other matters at present.) It will draw
“ attention to the subject, and science will gain by the
“ discussion.

“ When people think independently at different
“ times, and excited by different original subjects of
“ consideration, bearing on one more general object,
“ if their ideas converge towards one view of the
“ matter, it is a proof that there is something worthy
“ of further inquiry ; and if they think to any purpose,
“ it is hardly possible but that many points will occur
“ to each, which do not to the other, and that so a
“ theory may branch out and acquire a body much

“ sooner than it would do by the speculations of one
“ alone ;—and indeed such is in some degree the case
“ in the present instance. Babbage, for example, has
“ speculated not only on the heaping on of matter in
“ some parts, but on its abstraction in others, as a
“ cause of variation in the isothermal surface ;—and
“ justly ; it is a case of the algebraic passage from +
“ to — passing through 0. In envisaging (as the
“ French call it) the question algebraically, the cases
“ could not be separated. Again, he has confined
“ himself to the pyrometric changes in the solid strata,
“ while I have left these out of view, and relied on
“ what I think to be a far more energetic and widely
“ acting cause—the variation of pressure, and the
“ infirmity of supports broken by weight or softened
“ by heat, to produce *tilts*. Both causes, however,
“ doubtless act, and both must be considered in
“ further detail : the former alone may account for the
“ phenomena of the Bay of Naples ; the latter must, I
“ think, be called into account for those of Scandinavia
“ and Greenland, and of the Andes.

“ I would observe that a central heat may or may
“ not exist for our purposes. And it seems to be a
“ demonstrated fact, that *temperature does*, in all parts
“ of the earth’s surface yet examined, increase in going
“ down *towards* the centre, in what I almost feel disposed
“ to call a *frightfully* rapid progression ; and though
“ that rapidity may cease, and the progression even

“ take a contrary direction, long before we reach the
“ centre, (as it might do, for instance, had the earth,
“ originally cold, been, as Poisson supposes, kept for
“ a few billions or trillions of years, in a firmament
“ full of burning suns, besetting every outlet of heat,
“ and then launched into our cooler milky way) still,
“ as all we want is no more than a heat sufficient to
“ melt silex, &c. I do not think we need trouble our-
“ selves with any inquiries of the sort, but take it for
“ granted, that a very moderate plunge downwards, in
“ proportion to the earth’s radius, will do all we want.
“ Nay, the internal heat may even be locally unequal ;
“ *i. e.* great in Europe and Asia, small under America,
“ —as it would, for example, if, when roasting at
“ Poisson’s sun-fire, the great jack of the universe had
“ stood still, and allowed one side of our terraqueous
“ joint to scorch, and the other to remain underdone.
“ —A hint to those who are on the look out for a
“ cause (if any such there be) for the ‘ poles of max-
“ imum cold,’ and the general inferior temperature of
“ the American climate, from end to end of that
“ continent.”

NOTE K.

ON THE ELEVATION OF BEACHES BY TIDES.

IF the earth were a spheroid of revolution, covered by one uniform ocean, two great tidal waves would follow each other round the globe at a distance of twelve hours.

Suppose several high narrow strips of land were now to encircle the globe, passing through the opposite poles, and dividing the earth's surface into several great unequal oceans, a separate tide would be raised in each. When the tidal wave had reached the farthest shore of one of them, conceive the causes that produce it to cease; then the wave thus raised would recede to the opposite shore, and continue to oscillate until destroyed by the friction of its bed. But if, instead of ceasing to act, the causes which produced the tide were to

reappear at the opposite shore of the ocean, at the very moment when the reflected tide had returned to the place of its origin; then the second tide would act in augmentation of the first, and, if this continued, tides of great height might be produced for ages. The result might be, that the narrow ridge dividing the adjacent oceans would be broken through, and the tidal wave traverse a broader tract than in the former ocean. Let us imagine the new ocean to be just so much broader than the old, that the reflected tide would return to the origin of the tidal movement half a tide later than before: then, instead of two superimposed tides, we should have a tide arising from the subtraction of one from the other. The alterations of the height of the tides on shores so circumstanced, might be very small; and this might again continue for ages: thus causing beaches to be raised at very different elevations, without any real alteration in the level either of the sea or land.

If we consider the superposition of derivative tides, similar effects might be found to result; and it deserves inquiry, whether it may not be possible to account for some remarkable and well-attested phenomena by such means.

The gradual elevation during the past century, of one portion of the Swedish coast above the Baltic, is a recognised fact, and has lately been verified by

Mr. Lyell.* It is not probable, from the form and position of that sea, that two tides should reach it distant by exactly half the interval of a tide, and thus produce a very small tide; nor is it likely that by the gradual but slow erosion of the longer channel, one tide should almost imperceptibly advance upon the other: but it becomes an interesting question to examine whether, in other places, under such peculiar circumstances, it might not be possible that a series of observations of the heights of tides at two distant periods, might give a different position for the mean level of the sea at places so situated.

If we conceive two tides to meet at any point, one of which is twelve hours later than the other, the elevation of the waters will arise from the joint influence of both. Let us suppose, that from the abrasion of the channel, the later tide arrives each time one-hundredth of a second earlier than before. After about 3,150 years, the high water of the earlier tide will coincide in point of time with the low water of the later tide: and the difference of height between high and low water will be equal to the difference of the height of the two tides, instead of to their sum, as it was at the first epoch.

If, in such circumstances, the two tides were nearly

* See Phil. Trans. 1836.

equal in magnitude, it might happen that on a coast so circumstanced, there would at one time be scarcely any perceptible tide; and yet, 3000 years after, the tide might rise 30 or 40 feet, or even higher; and this would happen without any change of relative height in the land and water during the intervening time. Possibly this view of the effects which may arise, either from the wearing down of channels, or the filling up of seas through which tides pass, may be applied to explain some of the phenomena of raised beaches, which are of frequent occurrence.

Natural philosophers are at present not quite agreed upon the mode of determining the mean level of the ocean. Whether it is to be deduced from the averages between the highest and lowest spring tide, or from the averages of all the intermediate ones, or from the means of the instantaneous heights of the tide at all intervening periods—or by whatever other process, its true level is yet to be ascertained. It may, perhaps, also be useful to suggest that, besides the actual level of the sea at any particular place, it would be also desirable to ascertain whether the time of high water at given epochs is not itself a changeable quantity.

These reflections, however, are only thrown out with the view of exciting discussion on a subject involved at present in great mathematical difficulties, and possessing, at the same time, the highest practical importance.

NOTE L.

ON RIPPLE-MARK.

THE small waves raised on the surface of the water, by the passage of a slight breeze, are called Ripple ; and a series of, marks, very similar in appearance, which are sometimes seen at low water on the flat part of a sea-beach formed of fine sand, are called ripple-marks. Such marks occur in various strata of stone, and at various depths below the solid surface of the globe, and are regarded as evidence of their having been formed beneath the sea. Similar appearances occur when a strong wind drives over the face of a sandy plain, and are frequently seen upon the surface of snow.

It appears that two fluids of different specific gravity, the lighter passing over the surface of the former, always concur in the formation of ripple. It seems also

that the lines of ripple-mark are at right angles to the direction of the current which forms them.

If a fluid like air pass over the surface of perfectly quiescent water, in a plain absolutely parallel, it will have no effect; but if it impinge on the surface of the water with the slightest inclination, it will raise a small wave, which will be propagated by undulations to great distances. If the direction of the wind is very nearly parallel to the surface, this first wave, being raised above the general surface, will protect that part of the water immediately beyond it from the full effect of the wind, which will therefore again impinge upon the water at a little distance; and, this impact concurring with the undulation, will tend to produce another small wave, and thus, new waves will be produced. But the under surface of the air itself will also during this process assume the form of waves, and so, on the slightest deviation at any one point from absolute parallelism in the two fluids, their whole surfaces will become covered with ripples.

If one of the fluids be water, and the lower fluid be fine sand, partially suspended in water, these marks do not disappear when the cause ceases to act, as they do when formed by movement of air over the surface of water; but they remain and form the ridges or *ripple* which we observe when the tide has receded from a flat, sandy shore.

If, after the formation of ripple-marks at the bottom of a shallow sea, some adjacent river or some current deposit upon them the mud which it holds in suspension, then the first marks will be preserved, and new ripple marks may appear above them. Such is the origin of those marks we observe in various sand-stones, from the most recent down to those of the coal measures.

Dr. Fitton informs me, that the sand hills on the south of Etaples (in France) consist of ripple-marks produced by the wind on a very large scale. They are crescent-shaped hillocks, many of which are more than a hundred feet high. The height is greatest in the middle of the crescents, declining towards the points; and the slope on the inner side of the crescent, which is remote from the prevailing direction of the winds, is much more rapid than that on which it strikes.

Mr. Lyell has observed and described this mode of formation of ripple on the dunes of sand near Calais; remarking, that in that case there is an actual lateral transfer; the grains of sand being carried by the wind up the less inclined slope of the ripple, and falling over the steep scarp. I have observed the same fact at Swansea.

A similar explanation seems to present itself as the origin of that form of clouds familiarly known as "a mackarel sky"—a wave-like appearance, which pro-

bably arises from the passage of a current of air above or below a thin stratum of clouds. The air, being of nearly the same specific gravity as that of the cloud it acts upon, would produce ripple of larger size than would otherwise occur.

The surface of the sun presents to very good telescopes a certain mottled appearance, which is not exactly ripple, and which it is difficult to convey by description. It may, however, be suggested, that wherever such appearances occur, whether in planetary or in stellar bodies, or in the minuter precincts of the dye-house and the engine-boiler, they indicate the fitness of an inquiry, whether there are not two currents of fluid or semi-fluid matter, one moving with a different velocity over the other, the direction of the motion being at right angles to the lines of waves

NOTE M.

ON THE AGE OF STRATA, AS INFERRED FROM THE
RINGS OF TREES EMBEDDED IN THEM.

THE indelible records of past events which are preserved within the solid substance of our globe, may be in some measure understood without the aid of that refined analysis on which a complete acquaintance with them depends. The remains of vegetation, and of animal life, embedded in their coeval rocks, attest the existence of far distant times ; and as science and the arts advance, we shall be enabled to read the minuter details of their living history. The object of the present note is to suggest to the reader a line of inquiry, by which we may still trace some small portion of the history of the past in the fossil woods which occur in so many of our strata.

It is well known that dicotyledonous trees increase in size by the deposition of an additional layer annually

between the wood and the bark, and that a transverse section of such trees presents a series of nearly concentric though irregular rings, the number of which indicates the age of the tree. The relative thickness of these rings depends on the more or less flourishing state of the plant during the years in which they were formed. Each ring may, in some trees, be observed to be subdivided into others, thus indicating successive periods of the same year during which its vegetation was advanced or checked. These rings are disturbed in certain parts by irregularities resulting from branches; and the year in which each branch first sprung from the parent stock may be ascertained by proper sections.

It has been found by experiment, that even the motion imparted to a tree by the winds has an influence on its growth. Two young trees of equal size and vigour were selected and planted in similar circumstances, except that one was restrained from having any motion in the direction of the meridian, by two strong ropes fixed to it, and connecting it to the ground, at some distance towards the north and south. The other tree was by similar means prevented from having any motion in the direction of east and west. After several years, both trees were cut down, and the sections of their stems were found to be oval; but the longer axis of the oval of each was in the direction in which it had been capable of being moved by the winds.

These prominent effects are obvious to our senses; but every shower that falls, every change of temperature that occurs, and every wind that blows, leaves on the vegetable world the traces of its passage; slight, indeed, and imperceptible, perhaps, to us, but not the less permanently recorded in the depths of those woody fabrics. All these indications of the growth of the living tree are preserved in the fossil trunk, and with them also frequently the history of its partial decay.

Let us now enquire into the use we may make of these details relative to individual trees, when examining forests submerged by seas, embedded in peat mosses, or transformed, as in some of the older strata, into stone. Let us imagine, that we possessed sections of the trunks of a considerable number of trees, such as those occurring in the bed called the *Dirt-bed*,* in the island of Portland. If we were to select a number of trees of about the same size, we should probably find many of them to have been contemporaries. This fact would be rendered probable if we observed, as we doubtless should do, on examining the annual rings, that some of them conspicuous for their size occurred at the same distances of years in several trees. If, for example, we

* The reader will find an account of these fossil trees, and of the strata in which they occur, in several papers by Mr. Webster, Dr. Buckland, Mr. De la Beche, and Dr. Fitton, in the Transactions of the Geological Society of London, vol. iv. Series 2.

found on several trees a remarkably large annual ring, followed at the distance of seven years by a remarkably thin ring, and this again, after two years, followed by another large ring, we should reasonably infer that seven years after a season highly favourable to the growth of these trees, there had occurred a season peculiarly unfavourable to them: that after two more years another very favourable season had happened, and that all the trees so observed had existed at the same period of time. The nature of the season, whether hot or cold, wet or dry, might be conjectured with some degree of probability, from the class of tree under consideration. This kind of evidence, though slight at first, receives additional and great confirmation by the discovery of every new ring which supports it; and, by an extensive concurrence of such observations, the succession of seasons might be in some measure ascertained at remote geological periods.

On examining the shape of the sections of such trees, we might perceive some general tendency towards a uniform inequality in their diameters; and we should perhaps find that the longer axes of the sections most frequently pointed in one direction. If we knew from the species of tree that it possessed no natural tendency to such an inequality, then we might infer that, during the growth of these trees, they were bent most frequently in one direction; and hence derive an indication of the prevailing winds at that time. In

order to determine from which of the two opposite quarters these winds came, we might observe the centres of these sections ; and we should *generally* find that the rings on one side were closer and more compressed than those on the opposite side. From this we might infer the most exposed side, or that from which the wind most frequently blew. Doubtless there would be many exceptions arising from local circumstances—some trees might have been sheltered from the direct course of the wind, and have only been acted upon by an eddy. Some might have been protected by adjacent large trees, sufficiently near to shelter them from the rudergales, but not close enough to obstruct the light and air by which they were nourished. Such a tree might have a series of large and rather uniform rings, during the period of its protection by its neighbour ; and these might be followed by a series of stunted and irregular ones, occasioned by the destruction of its protector. The same storm might have mutilated some trees, and half uprooted others : these latter might strive to support themselves for years, making but little addition, by stunted layers, to the thickness of their stems ; and then, having thrown out new roots, they might regain their former rate of growth, until a new tempest again shook them from their places. Similar effects might result from floods and the action of rivers on the trees adjacent to their banks. But the effect of all these local and peculiar circumstances would disappear, if a sufficient number of sections could be procured from

fossil trees, spread over a considerable extent of country.

The annual rings might however furnish other intimations of the successive existence of these trees.

On examining some rings remarkable for their size and position, let us suppose that we find, in one section, two remarkably large rings, separated from another large ring, by one very stunted ring, and this followed, after three ordinary rings, by two very small and two very large ones. Such a group might be indicated by the letters—

o L L s o o o s L L o o

where *o* denotes an ordinary year or ring, *L* a large one, and *s* a small or stunted ring. If such a group occurred in the sections of several different trees, it might fairly be attributed to general causes.

Let us now suppose such a group to be found near the centre of one tree, and towards the external edge or bark of another; we should certainly conclude, that the tree near whose bark it occurred was the more ancient tree; that it had been advanced in age when *that* group of seasons occurred which had left their mark near the pith of the more recent tree, which was young at the time those seasons happened. If, on counting the rings of this younger tree, we found that there were, counting inward from the bark to this remark-

able group, three hundred and fifty rings, we should justly conclude that, three hundred and fifty years before the death of this tree, which we will call A, the other, which we will call B, and whose section we possess, had then been an old tree. If we now search towards the centre of the second tree B, for another remarkable group of rings; and if we also find a similar group near the bark of a third tree, which we will call C; and if, on counting the distance of the second group from the first in B, we find an interval of 420 rings, then we draw the inference that the tree A, 350 years before its destruction, was influenced in its growth by a succession of ten remarkable seasons, which also had their effect on a neighbouring tree B, which was at that time of a considerable age. We conclude further, that the tree B was influenced in its youth, or 420 years before the group of the ten seasons, by another remarkable succession of seasons, which also acted on a third tree, C, then old. Thus we connect the time of the death of the tree A with the series of seasons which affected the tree C in its old age, at a period 770 years antecedent. If we could discover other trees having other cycles of seasons, capable of identification, we might trace back the history of the ancient forest, and possibly find in it some indications for conjecturing the time occupied in forming the stratum in which it is embedded.

The application of these principles to ascertaining the

age of submerged forests, or to that of peat mosses, may possibly connect them ultimately with the chronology of man. Already we have an instance of a wooden hut with a stone hearth before it, and burnt wood on it, and a gate leading to a pile of wood, discovered at a depth of fifteen feet below the surface of a bog in Ireland : and it was found that this hut had probably been built when the bog had only reached half its present thickness, since there were still fifteen feet of turf below it.

The realization of the views here thrownout would require the united exertions of many individuals patiently exerted through a series of years. The first step must be to study fully the relations of the annual rings in every part of an individual tree. The effect of a favourable or unfavourable season on a section near the root must be compared with the influence of the **same** circumstance on its growth towards the top of the tree. Vertical sections also must be examined in order to register the annual additions to its height, and to compare them with its increase of thickness. Every branch must be traced to its origin, and its sections be registered. The means of identifying the influence of different seasons in various sections of the same individual tree and its branches being thus attained, the conclusions arrived at must be applied to several trees under similar circumstances, and such modifications must be applied to them as the case may require ;

and before any general conclusions can be reached respecting a tract of country once occupied by a forest, it will be necessary to have a considerable number of sections of trees scattered over various parts of it.

NOTE N PAGE 190.

ON A METHOD OF MULTIPLYING ILLUSTRATIONS
FROM WOOD-CUTS.

FINDING the number of wood-cuts necessary to explain the parts of the Calculating Engine considerable, and the expense great, it appeared to me that the method of copying by casting might, perhaps, be employed for the purpose of diminishing the evil.

The plan which occurred to me was, to make a drawing of that portion of the mechanism required to be explained, which should contain every part necessary for its action, and, in some cases, even the framework requisite for its support. Such a drawing would be far too complicated for the ordinary reader, and might appear confusion even to the contriver of the machine. This drawing was then to be sent to the wood-cutter to be engraved, and on its return, it was to be sent to the stereotype founder, for the purpose of

having any number of fac-similes made in type-metal. Now, each of these metallic plates would, like the original wood-cut, express the drawing in *relief*, and, by cutting away any line in the plate, that line would be removed in the impression.

The first thing to be done was, to remove from one of the stereotype plates every line, *except* those which formed the *framing* of the mechanism. The next step was, to remove from another of those plates *all* the framing, and every other line, except those which represented two or three of the principal wheels and levers.

If there should be many such parts, several plates might be taken, on each of which some few parts, not interfering with each other, might be allowed to remain. Other plates might then be taken, on which the parts given on two or more of the former plates, might be allowed to remain, and others again might contain combinations of three or more of these. Thus, by a series of plates, commencing with the simplest portions of the mechanism, we might gradually advance through the various combinations, up to the original wood-cut, which, by means of such steps, might be made perfectly intelligible.

The original wood-cut will be more expensive, on account of the additional work contained in it; but its

multiplication by casting is a cheap process; and the cutting away some of the lines of each plate, and dotting others, (by removing small portions at short intervals,) which might, in different plates, require to be represented as passing behind other lines, is not a work of much difficulty or expense. The number of illustrations, all printed with the letter-press, which this plan admits of, renders it possible to explain much more complicated machinery than could be accomplished by engraving, unless at an expense which would effectually preclude its application; whilst the successive picture of every wheel and lever, exhibited on separate plates if necessary, as well as of every one of the combinations which are employed, will render the machinery intelligible to a number of persons much larger than the class which usually studies such subjects.

The same principle may be applied to *coloured* geological sections and maps. The whole drawing having been sent to the wood-cutter, as many stereotype fac-similes may be made from his block as there are colours to be represented. One plate may then be taken, from which all the parts are to be scraped out which are not to be coloured brown; another may be taken from which all parts not to be coloured green; and so on for the rest of the colours. The perfect identity of the plates will render it easy to preserve what is technically termed *the register*, that is, to

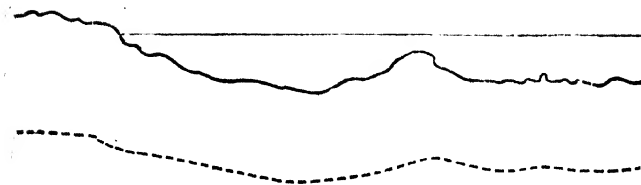

prevent the overlapping of any one colour on any other.

On the opposite page, the reader will find an illustration of this art; it is the same plate as that at page 190: it is not very favourable either as to the degree of difficulty, or as to the question of economy; but it is the only one that the subject of this volume admitted, and is quite sufficient to explain the principle.

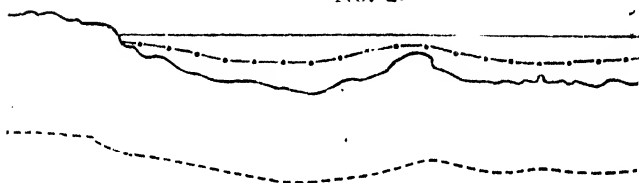

The figure at the bottom of the page, No. 4, is the impression from a stereotype plate, which is a facsimile from the original wood-cut, engraved for the illustration. No. 3, the next above, is the impression from another stereotype plate, from which the lines marked D and F, on No. 4, have been cut away. No. 2 is the impression from another plate from which the line E has been cut away; and No. 1 is an impression from a similar plate, from which the lines C and E have been cut out.

The four individual plates have been soldered together, and form the stereotype plate of the page referred to.

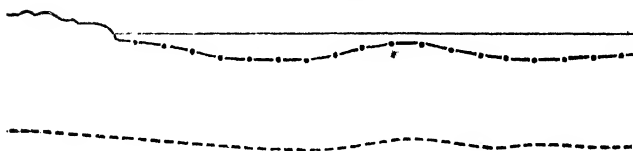

As the method here suggested is extremely simple, it is scarcely possible but that it must have occurred to others; and it may, perhaps — although I am not aware of it — have been employed on

some occasions. I have, however, thought, that in giving publicity to it, I should be doing a service to those whose writings require pictorial illustration, and especially to those who cultivate the sciences of mechanics and geology. Perhaps, also, the same system might be applied to multiply, at a cheap rate, the blocks used in colour printing, both upon paper and on woven fabrics.

THE END.
